PacketRadio is Still Alive.....Mississippi.....145.010.....Simplex.....1200 Baud
Hi Mike, I have not used that balun.
I have used others and find that I could not tell much difference in using a balun, but did seem? better.
I have attached a write up that pretty much , what I also think.
that is just my opinion.
I do like the Loop and found it to be quieter for me.
If you find any think else please share.

Rich,
Nice clean construction! N1LO describes the construction of a
switchable balun using toroid cores on
http://www.qsl.net/n1lo/n1lobaln.pdf
<http://www.qsl.net/n1lo/n1lobaln.pdf>
Essentially you are switching the configuration between one 4:1 Guanella
balun <http://qsl.net/kp4md/guanella.pdf> and two 1:1 Guanella baluns
in parallel.Some have voiced concerns that connecting two 1:1 baluns in
parallel compromises the reduction of common mode currents by decreasing
the common mode impedance
http://www.eham.net/ehamforum/smf/index.php/topic,74785.0.html
<http://www.eham.net/ehamforum/smf/index.php/topic,74785.0.html>
http://forums.qrz.com/showthread.php?257424-1-1-BALUN
<http://forums.qrz.com/showthread.php?257424-1-1-BALUN>
http://groups.yahoo.com/group/rsgbtech/message/2986
<http://groups.yahoo.com/group/rsgbtech/message/2986>
Perhaps this compromise is worth the convenience of such a neatly
switchable balun.

Carol, just a quick note on the two toroid or two rods. With my very limited test equipment, a MFJ-259, I have found that the rods gave me a wider range of low SWR reading into a dummy load.

I have seen the set up by N1LO.

I was looking for the ease of changing for comparison.

Thank you for the information I will look into it.

Rich , KdØzz , ☺

3990. 4:1x1:1 Balun Update

Yahoo group: SkyWires
Date: 2011-07-28 21:22:04 UTC
From: Richard Schmuke
Topic: 3990 Message: 3990

I completed my switchable balun, http://s1102.photobucket.com/albums/g453/KD0ZZ/
and hooked it to a 80M dipole fed by 450 ladder line. 18 inches of coax out of the tuner and then the balun. I was asked what was better the 1:1 or the 4:1. Well I don't know, this is my first ladder line antenna and the points of resonance are all over the place. These reading are direct without the tuner. It is into a 80M length dipole and the SWR is 7:1 at the 1:1 balun and SWR of 4.2:1 with the 4:1 at 3.8 Mhz. The 1:1 balun did have good points at 5.8,15.3 and 24.7 Mhz. The 4:1 was good at 11.6. 20.1 but what I really like is it is great right on 10M phone and with 10 opening up that will be used a lot. 1.1to1 at 28.5, 28.4 and 28.6 at 1.2:1.
With a tuner the bands can be set at for the rig to see 1:1. Are these readings normal for a 80 doublet fed with 450 ohm?

Rich , KDØZZ , ☺

3991. AW: [SkyWires] 4:1x1:1 Balun Update

Yahoo group: SkyWires
Date: 2011-07-29 10:13:00 UTC
From: Siegfried Jackstien
Topic: 3990 Message: 3991

Hi rich
Yes those readings are common
It depends on length of dipole AND length of ladderline
With several try and error you can get those "nice readings" closer or exactly in the bands ....

What you should not do is to have a low impedance point and then use the 1:4

Example halfwave dipole and halfwave ladderline OR fullwave dipole and quarterwave ladderline ... both would give you low impedance at the shack end

And lowering that further via the 1:4 would give you even lower impedance at the tuner end of the balun ... and most tuners have higher losses if tuned to very low impedance (for that you should use the 1:1)

Good setup is halfwave dipole for lowest band and a quarterwave line to the balun ... that would transform the low dipole impedance up to a few hundred ohms and with the 1:4 back down in the tuner range BUT try to avoid to get those resonances and transforming EXACTLY ... cause if the line is exact a quarterwave you can get VERY HIGH impedance (to high for the balun!) and you can have some very nice firework in your shack :-)

I had the same setup (dipole with ladderline) here for a long time and it is a very good multiband setup ... do not worry about the readings of your swr meter ... tune it and use it :-)

With some added knife switches you could even get rid of you tuner completely (with those switches you could ad some ladderline)
See here:
http://www.w5dxp.com/notuner.htm

I grabbed that idea and do nearly the same now with my topband deltaloop
With only 2 different length of ladderline I can work many bands without tuner!!
And on the other bands swr is between 2 and 3 (not in the hundreds) so there the tuner losses are also low ...

Good dxing with your multibander *g*

Dear Rich,
Yes, I've observed similar results, explained by the complex impedance transformations that occur. Your "points of resonance" will also shift as you vary the length of ladder line. W5DXP describes a clever way to use this to achieve a low SWR on all frequencies without a tuner at http://www.w5dxp.com/notuner.htm <http://www.w5dxp.com/notuner.htm>

From: cernem1alt
Topic: 3993 Message: 3993

I have just put a 36ft skywire loop in my attic fed by a random length of about 18ft of 450 ohm ladder feeder into a LDG 4:1 balun into my Yaesu FC20 tuner fired by my Yaesu FT-847 got 40m - through to 6m worked Italy on 6m and Spain on 20m on 5 Watts QRP!!love it!

So it shows even with the most restrictive of situations just what can be achieved and a great deal of the "rubbish" noise is just not there!
I am hooked

There's a good chance it's the same balun that is built into my MFJ-902H tuner, which is as good as any. MFJ has been building tuners with baluns for decades, so they know what they're doing. And baluns are not exactly rocket science in the first place.
That aside, I don't why this is an issue for you. I assume your longwire is non-resonant and requires a tuner. That will match the impedence of the wire, whatever it is, for the frequency you are on.
If the skywire is something other than a longwire, different story.
I have used W2AU and Hy-Gain and Palomar baluns, and those built into MFJ and Dentron tuners, as well as built my own from Amidon kits and from scratch. I have even used television receiver baluns (but they explode at about 35-watts). I cannot say that one is any better than another.
Paul, www.KC5JK.com

PS The Palomar (or any) baluns that have permanent wires coming out the body for the balanced side, and which cannot be opened to replace those wires, should never be cut, unless you first measure their lengths so you can splice same size wires back onto them later.

The MFJ-902 tuner is rated for 150 watts and the MFJ-912 is for 1500 watts.

Note: I have the MFJ-962D tuner and using balanced line with the built in balun I cannot get all bands down to 1:1. I use a foot of coax with my own external 4:1 balun and can tune 1:1. So with a tuner and the 912 should be good for full power.

> I have an older police scanner ...

There are scanner forums and websites that cover this better.

I think there are two or three different digital radio standards, one of them is P25 (Project 25). There are scanners that demodulate these too (even Radio Shack has a couple). But the digital modes allow encryption too, and if that is in use, even the P25-capable scanners would not work to receive those signals.

As for new frequencies, there will always be scanners made to pick up the bands in use. Various VHF and UHF frequency ranges have been used for years by law enforcement. Be aware that some re-banding (in the 700-800 MHz general area) has been taking place over the last couple of years, and some of the bands changed somewhat, yet again. Old scanners (newer than yours) might not work on all the latest bands.

4019. 40M Star Horizontal Loop in attic

Yahoo group: SkyWires
Date: 2011-09-21 14:47:42 UTC
From: kj4wrk
Topic: 4019 Message: 4019

Hi all,
Like many, I live in an antenna-restricted area and have issues with XYL impedance as well.

I wanted to put up a multi-band antenna in my attic and had considered a fan dipole as well as a few other designs. A conventional horizontal loop seemed to be a good antenna to try, but the available space was only about 30X30 feet, not enough for 40 meters.

I was curious about distorting the basic shape of the loop and what effect it would have on propagation. After a lot of googling, I stumbled across Cebic's web site and found his article on star horizontal loops (http://www.cebik.com/content/a10/wire/40star.html).

Since I have a two-zone heating and A/C system, I had to contend with the A/C unit in the attic, so a flat star loop wasn't possible. I ended up constructing a version of the star loop with the center sections pulled upwards into more of a pyramid shape. That way, I was able to put about 175 feet of wire into the space instead of 120 feet I could achieve with a regular loop. I'm feeding the loop with a direct-attached Balun Designs 4:1 balun through about 50' of RG-8X to a LDG AT100ProII tuner and my FT-897D.

Performance has been good considering the antenna is about 20 feet off of the ground for the lower portion of the stars. I'm able to make contacts into Eastern Europe, Canary Islands, South America and the Western USA on about 30 watts on 40m - 10m. My only 6m use has been into a local repeater, but when band conditions warrant, I'll try longer distances.

Steve, sounds very similar to what I installed in our CCnR home 20 years ago. Our attic could take a 40x20' loop. I fed it with ladder line down thru the wall to a 4:1 balun and short run of coax. I found that transmitting on 15m set off the horn on the alarm system but a few chokes in the alarm box took care of that. I later made a delta loop outside of #18 copperweld fed in a lower corner with a 4:1 "remote" balun. The apex of the loop was about 20' at the top of the chimney. The base ran along a wooden fence in the back yard. No one notice or said a thing. It worked as well as the indoor loop and kept the rf further from the family. Finally I enlisted a fir tree on the corner of the lot and strung a similar slanting delta loop around the property. This time it was an 80m loop and was generally 1-2 s units stronger on receive than the indoor 40m loop. Using the #18 wire, no one said a thing. It is hardly visible until an ice storm coats the wires!

4022. Telephone "C" wire

Yahoo group: SkyWires
Date: 2011-09-30 05:48:59 UTC
From: Kenneth
Topic: 4022 Message: 4022

I have a large spool of telephone rural "C" wire (that I found in the forest, ahem :P) that I want to use for my 40M horizontal loop. It's 19ga 2-conductor copper-clad steel with nylon insulation and nearly impossible to work with! My question is, even if I short the 2 conductors at both sides of the Ladder-Loc feed point, will I still have a problem with the distributed capacitance affecting my radiation pattern? Am I overthinking this? Thanks!

To answer your question, no. The original owner of the group left without giving one of the moderators full control of the group. Just as any of us did not have to be approved to become members of this group, the same is also true of the hit and run spammers. The moderators can only react after the fact, as one of the moderators I wish we could change the group to where it would required approval but we can't. I am also a member of another group called Loop Sky Wires, that group DOES required approval to become a member. As you probably might guess, there is almost no spam in that group, and if it happens it is usually dealt with quickly. You are more than welcome to join that group, who knows, I might be one of the moderators that will be approving you there. Hope to see you there.

4047. RF InShack with 160m loop fed with ladderline need help

Yahoo group: SkyWires
Date: 2011-10-16 00:44:17 UTC
From: Don
Topic: 4047 Message: 4047

I have built a 160m loop and am feeding it with ladder line.

The ladder line comes in directly thru the window and is connected to my MFJ 962d tuner balanced line. I can tune the antenna with no significant issues at all for SWR.

The rest of the set up is a K3 to an SGC powercube. Power is provided by batteries.

The problem that I am having is I am getting a significant amount of RF problems with a highly distorted TX when I use the loop.

Now there is another thing that needs to be stated about the installation. The loop runs around the house so that the shack is basically in the center of the circle. Also I have a dipole that is close to the loop as well. So I don't know if the RF is coming in thru the dipole. Note if I TX with the dipole there is still RF on my signal but highly reduced. If I disconnect the ladder line from the tuner the RF goes away. (Maybe a tuner problem???)

Right now to be able to use the radio at all I had to remove the ladder line from the shack and I have coiled it up outside at the feed point.

So can this installation be salvaged, as I am thinking my number 1 problem is that I am in the center of the loop. Second I am starting to think from reading on the internet that ladder line should not be run in the shack as any RF can not be choked. Thus I should be using a 1:1 current balun outside of the shack and then run coax between the tuner and balun and I would suspect put some ferrites on the coax.

Anyone who can provide help in figuring out this problem that I am having your feedback will be appreciated.

Thanks
Don

From: Dr Don
Topic: 4047 Message: 4049

Another thing to try is to end the ladder line outside the shack without any coil.
Use two parallel pieces of coax from the ladder line to the tuner.
The center conductors go to the ladder line and the tuner.
The shields are tied together. The ladder line end is floating and the tuner end
is connected to the shack ground.
I would also ground the dipole center and shield to test that it is not affecting the
problem.

Dr. Don HC4/W4BWS

4054. Advice please on 10w tx/rx horizontal loop for HF Amateur use.

Yahoo group: SkyWires
Date: 2011-11-15 14:54:28 UTC
From: dj_philonline
Topic: 4054 Message: 4054

Hi, posted this on another site but received no answers so here goes, I have started using loops since moving into a new qth in a deep valley town
in Northumberland with lots of overhead domestic 240v and telephone cable networks making HF work nearly impossible, my vertical loop which is big enough (6m x 3 in a delta config.) to cause a stir with the elderly locals is great for 20 to 10m bands but with 5w from my FT-817ND the tuner losses are so great on 40m it is hard to get a good swr reading, I have come up with a plan to put a horizontal loop just inside the top lip of my plastic guttering which surrounds my semi-detached house. Looking for 40m and 80m work on this antenna.
Questions
1: would the loop coming through the loft at the house attached end reduce its performance much?
2: would the 4:1 balun be better located in the loft or outside at the unattached end of the house?
3: would I be better having it as a horizontal dipole centre fed at the unattached end of the house and coming back on itself around either side of the building and not feeding into the loft at all?

I hope these questions are understandable or I will have to try and do drawings and that will not be good, I would rather stick to the loop idea if possible as the reduced noise floor level is fantastic compared to all other types of antennas tried at this location.
Hope somebody can advise.
regards
Phil M6MRP

I agree with Dr Don you need to get that ladder line outside the shack away from close objects, I have tried this before as it is easy to feed flat ladder line trough a window but as the ladder line is actualy an active part of the antenna not realy a feeder you are creating a disturbance in its radiaton field by bringing it through the window, I solved the problem by feeding with a short length of RG58 to a 4:1 balun wound on to about 7 inches of white waste water pipe about 2 inches or less in diameter, very easy to build out of scrap stuff and it worked a treat hanging outside the window from a wooden dowling 12 inches long stuffed into a small hole drilled into a brick, there is a very good web posting showing step by step build if you need it give me a shout and I will hunt the link down for you.

Topic: 4056 Message: 4056

http://rogertango.com/articleread.aspx?idnumber=34232411

This is the exact same design I used for 50 ohm coax to ladder line dropper, worked a treat untill I had to move qth into this RF dead hell hole, I did not use any fancy cable clamps or even a socket just the plastic maste pipe from a skip, scrap wire and solder joints well sealed with tape cost nothing.
Hope it helps somebody

Does not matter but will influence lobes on the higher bands
Weatherproofing it is a thing to think about

> 3: would I be better having it as a horizontal dipole centre fed at the
> unattached end of the house and coming back on itself around either side
> of the

See above
...

If you have only room for a small loop and wanna use it on half ist design
qrg
Just open the opposite wire (bridge with banana plugs or similar) and use it
as "bent dipole" on the lowest band
Example : you build a 80m loop
Open it and you have a bent 160m dipole
But then you have to use a length of ladderline for feeding that dipole/loop
combination multiband

Attachments: 2 described; binary payloads are missing from this source WARC

What size is your loop in length? If you want to work 80 and 40 with a 4:1 balun you need a loop 175m in length , with a 87m length loop you can work 80 with a 2:1 balun and 40 with a 4:1 balun.

Thanks for the input Sigi, I did look at the idea of an open loop and even purchased a relay to do this but the use of ladder line at this qth is out of the question so I think the loop fed through the loft will be the way I will try first.
regards

Hi Rich and thanks for the input, I think I am only going to have about 52m max to play with so this could be a non starter, I have seen plans for a switchable 4:1 to 1:1 balun but not a 2:1 so I will have to do some research on that one, putting the balun feedpoint into the loft would also make remote relay switching between balun windings much easier its just a shame I do not have the room for the 87m version, my 18m length vertical loop will tune to the 40m band with my mfj on my FT-840 at a higher power level than the 817ND giving great RX but the TX performance is very poor compared to the 10m to 20m bands.
regards
Phil

Phil , I built my own switchable balun, 4:1 or 1:1 for coax to 450 ohm line. This is used on a 135 doublet. The design is a current balun, the 2:1 I built is a voltage balun. If you run across a switchable with a 2:1 please let me know, I would like to try it.

Back to the loop, what I did was put up a 80m band size loop then with a 4:1 balun tweaked it to a 1:1 SWR in the middle of the 20M phone band and use it 40 thru 10. It work great 40 thru 10, not good on 80. It is coax fed the balun at the apex.

Rich , Kd0zz

From: klauber.alex
Topic: 4066 Message: 4066

Greetings! I just wanted to introduce myself to the group. My name is Alex and I live near Syracuse, NY. I have been a shortwave listener for 34 years. My first radio was a Realistic DX 150. That radio opened the door for me to discover shortwave and utility stations. Next came a Realistic DX 302. I loved the frequency counter on that rig. Never again would I use a radio without a digital display.
Currently I am using a Radio Shack DX 398. I'm not partial to Radio Shack receivers, it's that I had a store close to my home and it was convenient. Most of the radios were purchased on a whim.
I use the DX398 with a long wire antenna. Antennas are one of the most enjoyable parts of this hobby, but for me. Experimenting with different lengths of wire, molded into the various shapes to see, hopefully, an improvement in a stations signal.
I have only now begun to collect QSL cards from my contacts. Nothing exotic yet but I'm working on it!

Hi

I just want to introduce myself.
My name is jens / OZ1QSQ I live in Denmark, as the callsign tells, on a small farm in the countryside.
I just went into HAM radio three years ago, so I am no elmer. I have a couple of radios, the jewel piece is my Kenwood 2000.
Last winter I had a experimental hook up 160m loop and now I feel the need to make a permanent solution, as the experiment has dropped to the ground literally! I am so found of this antenna I simply has to erect a new and better version of it ASAP.

4068. 2λ 160m skywire loop?

Yahoo group: SkyWires
Date: 2011-11-27 00:27:15 UTC
From: Jens
Topic: 4068 Message: 4068

Hi

I am all new in this group, so i will plunge into it feet first. I am sorry if this question has been raised a hundred times, but I don't know what to call this antenna - please feel free to point me into the right direction if there are an old thread dealing with this.

I have had a full wave 160m horizontal loop hanging from my garden trees most of a year. But now the sun and wind has all but cut it completely down - time to make a new and improved version.

I have a supply of 50'(15m) wood masts at my disposal and I aim on a new loop antenna with Litze wire and true ladder line feeder.

Two questions for the honored members:
1) Is there any gain in making a double wavelength loop? (pros/cons)...

2) How do I calculate the tension on my antenna wire hanging i a pentagon shape?

Hello Jens,

RE (1), there is advantage in using a 2WL loop over a 1WL in terms of lowering the TO (Take Off) angle of radiation. At 1WL, especially at such a low height in terms of %WL above ground, the antenna will be a very effective NVIS (Near Vertical Incidence Skywave) antenna. Lowering the TO angle of radiation may help to increase the TX range of your antenna.

On the (potential) downside, the 2WL loop as compared to the 1WL loop may not be as effective if used on the upper HF bands due to sharp peaks and nulls in the radiation pattern. This is not a problem if your primary use is the 160Mtr and other lower HF bands.

There are some excellent articles on horizontal loops available at www.cebiksite.com which describes the effect of loop circumference and height above ground on many aspects of loop performance.

There is also an excellent utility I have used "rjeloop4.exe" available from <http://www.smeter.net/antennas/large-transmitting-loop.php> http://www.smeter.net/antennas/large-transmitting-loop.php that helps model many of the parameters involved, without the need to use a heavy duty modelling program.

RE (2), an interesting question. one that I do not know the answer to, but I went looking and found a related article at http://www.idahoforests.org/img/pdf/lessons/calibration.pdf The formula on page 58 might be useful?

Regards,

Michael

Hello Michael

Thank you for your reply. I did know a couple of the links you gave me on question 1, and they are great resources. I will study the rest with great interest.

On the other matter of calculating the tension in the wire, the formula do not produce accurate results.
The load on the wire is not a point load, but a distributed load over the entire length of the wire. And as a result the wire does not hang down in a triangle (obviously). As I recall it it is a shape called a hyperbolic "something"... It gently slopes down.
So the angle of attach on the mounting point is not the same as if it were a straight line down to the load.
Once this angle and force is calculated, you can determine if your wire is strong enough.
Problem is I don't know how to do it :-(

To determine the static mast loading, the trick is to calculate the angle of attack on the mounting point and do a simple enough vector force calculation on the mounting point to get the load on the mast.

To spice it all up, you just add a pinch of wind load and you are cooking :-)

The reason I would like to know these forces, is that I plan to tension the wire by a live mounting point in the top of the masts, and then run a rope down to a counter weight near the ground.
The heavier I can make the weight, the more linear my wire will hang.

Best

Welcome Jens

Name here is John qth is West Monroe,La. I to love the loop antenna I have a 80 meter and 40 meter loop.
I would think winter is very hard in Denmark so every thing needs to be heavy duty. I am able to use trees as supports and 14 ga wire here we do not not have vry bad winters. I also feed mine with 450 ohm ladderline to 4:1 balun and abt 20 ft of coax. I plan on next spring putting up a few more. My 80 meter slopes down from abt 80 feet to 20 ft facing northeast I get into Europe very well.

Again nice to meet you good luck with your project.

Good day Sir, thank you for the link. VK1OD has a wonderful assortment of information.

A note about words, around 40 years ago there was some research done on generating a radius when machining metal that would give better fatigue life. It was a catenary shape but at that time is was called a Grazinski radius or fillet. You could have done a search on it up to a couple of years ago. Someone by that same name made a stupid mistake and then won a law suit. Now all you get is information about her law suit.

Rich , KDØZZ , ☺

I know that you believe that you understood what you think I said, but I am not sure you realize that what you heard is not what I meant

Hello Rich

Aaaah the power of words :-)
Thus we arrive at http://www.vk1od.net/calc/awcc/awcc.htm where some brilliant HAM spirit, already presents the perfect online calculator.

Thank you
Jens / OZ1QSQ

Jen, I run a 160m horizontal loop here in Montana..I use dacron rope and suspend from trees. It varies in height from 30-55 ft. I does really well on 80, 40, 30, and 20 meters. 160 if good up to 400-600 miles. I also feed it with 450 ladderline to a 4 to 1 balun to rg8x to my tuner then to 746pro. It was 80 meter loop for a couple of year but I doubled the size and it helped alot..73, Alan

4076. 80m Skyloop Question

Yahoo group: SkyWires
Date: 2011-12-03 03:59:37 UTC
From: Mac
Topic: 4076 Message: 4076

Hello All,

I have a 80m skyloop strung in the trees in my back yard. It's currently 287' in length as when I built it, I took the recommendation to cut it for the lowest frequency (3.5MHz in this case) and tune up to other freqs with a tuner.

I used the formula 1005/freq (3.5) yielding 287'.

I now find myself working mostly on 3.9MHz SSB. Would I see any appreciable improvement in performance at 3.9 MHZ if I shortened this loop by 30 feet to 257'? (again using the formula 1005/freq (3.9) yielding 257')

I feed this antenna via 450 ohm ladder line into a 4:1 voltage balun, then into the rig via 3' coax. My tuner is a Kenwood AT-200.

Appreciate any advice and comments.

Mac / K6OVI

The Kenwood tuner will only match up to a 3 to 1`mismatch. So if it matches
now you probably will not see much difference.
Trimmimg to the upper end of 80 meters may effect a match on higher bands.
If you were using coax feedline yoou would ne3wd tio trim it but with 450
ohm lead and balun length is not so critical.

4078. Re: [SkyWires] 80m Skyloop Question

Yahoo group: SkyWires
Date: 2011-12-03 18:35:38 UTC
From: Andy
Topic: 4076 Message: 4078

Antennas do not need to be resonant to be effective. Non-resonant antennas radiate just as well. The most noticeable effect, is in the impedance/VSWR. The radiation pattern also alters, depending on how far off-resonance one is. 3.9 vs. 3.5 is not enough to make a huge difference in that, I think.

I wonder about the recommendation to cut it for the lowest frequency. What I have seen, is that one wants to cut a loop for the lowest frequency BAND in which you intend to use it, but not for the lowest frequency within that band. For example if you wanted to do 80, 40, and 20 meter bands, cut it for 80m and you can use it on the others. Whereas, if you cut it for 40m, it would not work so well on 80.

It might not hurt to trim it shorter, but I don't think you'd see it performing better. Then again, on harmonics the difference multiplies, so you might see a bigger difference there, not necessarily in your favor, in the SWR if nothing else. And there's also things like the ladder line and balun to consider.

Andy

Subject: Re: [SkyWires] 80m Skyloop Question

Has anyone ever done radiation patterns made by loops like these? We all have seen the patters of dipoles when used like this, but i do not ever remember seeing what patterns happen with loops.

Joe WB9SBD

Joe, here is a link to some patterns for a delta loop, I put one up just like it in shape but not as high, I love it and don't intend to change until someone installs a 200ft tower for me with a set of mono-band antennas.

http://www.m0mcx.co.uk/?p=138

I have had verticals and dipoles, once I put up the loop I started getting good results in DX pile ups for the first time. I work all bands 40 thru 10 on it.

4085. Terminated Long Wire

Yahoo group: SkyWires
Date: 2011-12-17 16:00:24 UTC
From: John
Topic: 4085 Message: 4085

Is there any truth to the rumor that installing a 250-600 Ohm resistor between the far end of a long wire and a ground rod will reduce or eliminate the white noise that makes a longwire/random wire antenna unusable? I have used a counterpoise, and while that makes the wire more tuneable and vastly reduces RF in the shack, the wire is essentially a noise generartor.

How high above ground is it? My understanding is that Beverages and long wires use far end termination with a resistor in that range to make them unidirectional instead of bidirectional. I don't know about making them lower noise (unless the noise is coming from the backend.)

From: erickson.john20
Topic: 4087 Message: 4087

Hello Everyone:

Just received my General license after being away from Ham radio for 45+ years. Setting up a Kenwood TS-520 HF station and want to use a Sky Loop as my only antenna. First design is 350' long about 30' high shaped close to a "square". Will feed with 450 ohm ladder liner to a 4:1 current balun in my attic, then a short 10' piece of RG 58 coax to a MFJ 929 tuner in the shack. I'm concerned that it's not cut to any of the Ham frequencies (don't want to create any weird harmonics). But then there's lots of info saying "Go as Big as you can and let the tuner do the rest". Will only run 90-100 watts max mainly on C/W. I will be using oak trees (will use a tree service to climb the trees and set up the eye bolts and insulators/dacron rope) and 2nd story of the house to support the antenna wire. Want to use this set-upon 80-10 meters. Not planning on 160 meter operation at this time, but any chance of this working at that frequency too?

Second design is a full wave 80 meter Delta Loop, 275' total length, resonant at 3.65 mhz. Close to a triangle in shape, same height and same feed line. I'm pretty sure this would work 80-10 meters as cut.

QTH is at 1900' elevation on a ridge. I would really like to set up the larger loop, but have the concerns noted above.

Any input would be greatly appreciated

John, KJ6TBD

Either one will work well - especially if you are working relatively close stuff on 80M - but you can work DX with it on 80M. I use it for FD and always a dynamite antenna capable of holding a frequency all day/night on 40M. Good DX too. The square works best. I don't use a balun, just a tuner. You can shorten up the loop to approximately 250-270 feet.

Thanks for your reply Scott. I can't really shorten the 350' loop due to the way my oak trees are situated on the property. That's my concern, in order to create the "square loop" it has to be that length. I don't want to use masts or other supports. So....even though it's not cut right per the formula will I have problems with it? Thanks, John

Topic: 4087 Message: 4090

Just might be a bit harder to match. I use trees myself - for FD, we have it in a square - but the distance from a tree and a corner is maybe 50+ fee or so. You might want to consider lofting a line over the tree - that what I have done - a lot cheaper than a tree service.

Have you tried an ELNEC analysis of the desired dimension?

Scott
I'm just getting back into this after a 45 year absence and still have lots to learn and relearn!! I haven't tried any modeling programs for this design. I just posted a drawing in the "Files Section" so everyone can see what it looks like. "350' Loop" is the title. Lots of other factors to consider such as Lightning protection and static build up. Thanks again for your replys

From: John Wilson
Topic: 4087 Message: 4092

Hello John

Glad to see you are back in the hobby, I had a160 meter zepp up added abt 30 feet of wire to make a loop.
The loop highest point is abt 70 feet and the lowest is abt 20 feet.It is shaped like a sloping delta loop. I love this antenna it works well with my out board tuner it is feed with ladderline to 4 to 1 balun. I worked India first time ever\on 10 meters with my Yaesu ft-450 abt 90 watts. Last night on cw 80 meters worked several Dl and OE stations, getting 579 589 signal rpts. I have never been able to work Europe with that kind of report on 80. Anyway good luck with antenna .

John,

The day I made my homemade slingshot for antenna hooks changed antenna installation in a profound way for me. Even in my small town, I was able to buy a slingshot from a pawn shop, then I duct taped a fishing reel to it. I tied a light oblong fishing weight to the fishing line. When I pull back moderately on the sling shot, I can place the light weight remarkably accurately into a tree as high as 100 feet. After that you alternately pull up thicker and thicker rope until you have a large enough diameter rope in place, sometimes over the very top of a tree, to hold a loop corner.

That's when I learned how important height can be to make loops work better.

My biggest problem using loop antennas seems to be my tuner. You need a (preferably balanced) tuner that can match a wide range of impedances. If you don't have this, then you may need to try different lengths of ladder line to hopefully change feed impedance for any given frequency so you can tune all ham bands equally well.

I saw an interesting design using knife switches and different lengths of ladder line to tune for all the bands without a tuner at all.
Can't remember where, might have been the ARRL antenna book?

Idea is you cut different lengths of ladder line to switch in with you feed line that tune it for that band.

FYI

4098. G'day New Bloke

Yahoo group: SkyWires
Date: 2012-01-07 07:23:08 UTC
From: vk4oc
Topic: 4098 Message: 4098

G'day I have just joined this group and found some very interesting ideas about our Sky Loops.
I've enjoyed using a loop for quite a few years. My loop is 273 feet long in the config of a square, 4 sides of earth wire.I can only get my antenna up on poles about 10 feet.My feed line is 27.85 metres long of RG6 75 ohms and goes though my AT230 antenna tuner.My VSWR on 40 metres is 1.1 ,80M 1.7, 20m 1.5, 15m 1.7. 10m 2.6.VSWR.

In the Arrl book, I worked my formula 1005/F which was 3.600mhz. works out 279.166 feet.
I've worked a lot DX on my loop.
Cheers
Dennis vk4oc.

Hi Jens,

Is this antenna intended to transmit your signal? If you like to receive 160 meter or higher I can propose a different antenna wich is has a much lower noise level and better S/N and is significant smaller in size. I always use an different antenna for transmit and receive as i found that several types of receive antennas are much more suitable as they are less sensitive to several sources of QRM.

4104. Save BNR Radio Bulgaria on shortwave and medium wave

Yahoo group: SkyWires
Date: 2012-01-19 03:28:39 UTC
From: Al
Topic: 4104 Message: 4104

Apologies if is a little off-topic, but still related to radio communications. It is just that I would hate this shortwave station to vanish from the air waves like it has happened to others.

Spread the word please.

Alvin Mirabal

Save BNR Radio Bulgaria on shortwave and medium wave

Dear listeners and friends of shortwave and Radio Bulgaria, With a huge regret I'd like to inform you very bad news.
After more than 75 years in the world broadcasting from January 31, 2012 at 2200UT Radio Bulgaria cease broadcasting on shortwave and medium wave.

The shortwave transmitters in Kostinbrod & Padarsko will be destroyed in the next few months.

Radio Bulgaria is not necessary now to its shortwave and medium waves listeners.
The reason

No money for broadcasting on shortwave and medium waves. And who listens to short waves today?
We have internet. Maintaining the shortwave transmitters was "Mission Impossible"! Hope dies last.

As a frequency manager in the last 19 years my main task was to provide best quality signal of Radio Bulgaria in worldwide coverage.
There will be no shortwave, there will be no frequency manager. For all people who work in Radio Bulgaria that bad news is shock and horror. Beginning of the end. But we expect your moral support.

What can you do?

I posted a set of pictures if needed on Photobucket. The radio was not in use for about 7 years when I lived in a restricted area. I retired, moved, then in the summer of 2007 I sent the radio to Communications Services and had it gone thru by Cal Fisher NF5P. It was all checked and recalibrated and came back at 105 watt CW.
It has been run on SSB all the time so never at full power CW.
Original book, shipping foam and boxes, power cord, mike plus the computer interface cable.
Built in antenna tuner. S/N 603000xxx I have seen clean rigs like this go as of late for $550. Never been to field day with it , I have a TS-430 for field day. I just ordered a TS-590S and need to room.
I am asking for $500, OBO, plus shipping to you location.

Hi,

  Just writing to let you know our trip to Madrid, Spain has been a mess. We were having a great time until last night when we got mugged and lost all our cash,credit card cell phone. I was hit at the back of my neck with a pistol. We have reported to the local Police and have also contacted the consulate but was told to hang on for some couple of days before this mess can be straightened out Our return flight leaves in few hours from now. It has been a scary experience but thank God they didn't hurt anyone except me or take our passports away from us.

As we speak i need $1,500 USD to add up and sort my bills ,don't worry i will def refund it as soon as we get home,you can have it wired to my name via Western Union I'll have to show my passport as ID to pick it up here and i promise to pay you back as soon as I get back home.Here's my info below:

Name: Ken Burchfield

Location: C/Josefa ValcÃ¡rcel 40, 1a planta 1, 28027

Country: Madrid, Spain

Amount: $1,500

As soon as it is done, kindly get back to me with the confirmation number. Let me know if you are heading to the WU outlet now?

Many Thanks,

Ken.

On the recommendation of various people I have bought myself an AIM 4170C antenna analyser. It looks a nice bit of kit, but I am new to amateur radio and have an immediate question. At the moment I have a 25 feet to 35 feet high horizontal quad loop of about 490 feet in length. I have built it so by lengthening or shortening the guy ropes at the corners i can maybe add another 30 feet of wire, or lose as much as i want, with longer guy lines. i cannot get it higher unless i get some super tree fertiliser! It feeds off a corner into my bungalow through an upper window, via 450 ohm (I think...) one inch wide windowed ladder line of about 20 feet in length. probably 12 feet are superfluous, and just hanging in the breeze right now. This goes straight to the two screw terminals on the back of my Yaesu FC-902 ATU, which are designated for a "wire antenna". one of the posts is grounded. The ATU then goes to my old FT-902DM transceiver. The analyser has a SO-239 socket on it for connection to the DTU. How should I be connecting it to my antenna system? I think I may need something like a 4 : 1 balun at the house end of the ladder line, then connect the analyser via a short piece of co-ax to the balun, which in turn is connected to either "side" of the loop antenna ladder line? Or have I got this wrong? Is there an easy way to connect the ladder line so it terminates in a PL-259 plug, or is this an incorrect way of measuring things? I wiah to use the loop on HF multi band and in particular see if it can be optimised for either 160 meters or for PSK31 digi modes on either 20 meters or 15 meters. At the moment the AIM 4170C is probably 100 times more complicated than I am comfortable with, but I thought buying something really basic may be false economy in the longer term, as I feel I could get quite into this hobby. Thanks.

Hello chris

You need a balun (either external or built in the tuner)

I have a fc901 tuner (modded by dg9bfc!) ...

I disconnected the one wire terminal in the tuner and also disconnected the ground connection next to it

Then I added a 1:4 at the tuner inside ... connected to that one wire as input ... and the 2 output wires then connected to the 2 terminal posts (red and black) ...

I made another ground connection with a 6mm screw on a different place at the backside ...

When I wanna use the tuner for a longwire (were I would need that one wire terminal) I just use one of the coax outlets and a banana plug

Now I have 3 coax and one balanced output at that fc901

You can also put your balun external ... but there is so much room in the tuner I could not resist to put it in there

My coil-switch once broke and I hade to make a new one in ... a friend gave ma a nice switch with a lot more contacts that I had before

Now I have 16 positions on the coil ... makes tuning fast and easy ... also on the warc bands

That switch has only one row (instead the 3 rows in the yaesu tuner)

But 2 of that rows were only used for the "bridged" position of that tuner (cause you have one you know what I mean!) and that could easy be made with a second switch (dpdt located at backside right above the swr bridge)

No more turning around the whole circle when switching from a coax antenna (tuned for a given band) to the ladderline fed dipole or loop ... just change antenna switch position and grab over the tuner and flip that bridging switch (without turning the coil-switch!)

I have a (tuned) vertical for 20 and my ladderline fed loop

Sometimes during a qso condx change and the signal that was high on the loop is the high on the vertical

Switching from one to the other without turning the coil-switch now goes very fast (and sometimes I find tuning positions were I do not even use the bridging switch and have low swr on both antennas)

I will send you 2 pics of my modded tuner ... maybe then you also will make the balun inside

Greetz

Sorry for slow reply, my wife's father is poorly so we are a bit
distracted at the moment.

Thanks for the detailed answers, and the photos of how you modded you
ATU. I think I will do a similar modification, thanks for sharing this
excellent idea, I hadn't realized just how much unoccupied space there
was in there! I'll see if I can have a go at this over the weekend,
all the best!

Good that I could help you ...

Yes ... there is much room in the tuner for adding a balun

Good luck and keep me informed about your moddings :-)

Hope that your wifes father is well soon

4129. SWR & the Loop Skywire

Yahoo group: SkyWires
Date: 2012-06-04 17:20:44 UTC
From: Mark
Topic: 4129 Message: 4129

I put up a 40 meter loop over a year ago and for months it was all anyone could ask for in an antenna. I was off the air for about 2 months and when I came back I couldn't seem to make a contact with the thing. My 17 meter vertical is working like a champ. For giggles I connected up an analyzer and got an SWR reading of between 3 & 6 to 1.

Is there something I'm missing/don't know/should look for? Could foliage be causing my issue?

Thanks!

How is it fed, any corrosion, any coax in the system get water in it? I had some twin lead go bad from the wind and on a different antenna had some 9913 get moisture in it. Foliage should not be that big of a problem on 40. Please keep us informed.

4131. Phone line antenna

Yahoo group: SkyWires
Date: 2012-06-08 23:11:06 UTC
From: Bob Zimmermann
Topic: 4131 Message: 4131

Hello everyone,

I'm new here so i hope this is the right place to post this.

Has anybody ever used a phone line for an antenna?
I accidentally found a document on the net
(http://www.rdrop.com/users/billmc/phoneline.pdf)about doing this.
I found it interesting becouse when i was in my early teens i on
occasion would use an a/c line cord for an antenna. Yes i know that's
kind of unsafe and you are right.

!!!DON"T TRY THIS YOU COULD GET ELECTROCUTED!!!

but it does work, as long as you use a battery powered radio ,and ONLY ONE of the 2 leads from the a/c outlet AND you are NOT GROUNDED or Touching any metal. In other words if there is no path THRU you to anything else.

So the idea of a phone line is interesting.
Any thoughts?

That link is dead, however the idea sounds interesting,
as the power companies are thinking of broad banding the power lines
or I think I saw something to that affect a little while back.

From: Andy
Topic: 4131 Message: 4133

I can't get to the link either, even after removing the ")about" from the end of it. The PDF file isn't there, or is protected.

I assume you mean a receiving antenna ONLY, right? I definitely do NOT recommend sending any amount of RF energy into a phone line. Aside from safety issues, with today's electronic phones that would be just asking for trouble, even at 'QRP' levels.

I had crystal radios as a kid, and they worked like gangbusters when clipped to the finger stop on our dial telephone. It was one of the best antennas I found for those radios. I assume it is electrically connected to the phone chassis, which is probably capacitively coupled to the phone line.

If your utility lines are above ground (as ours are), a phone line might make a pretty effective longwire antenna.

OTOH, if you have DSL in your area, you might want to avoid this.

I also have some experience with the AC line as an antenna. As a teenager I built a zip cord coupler (following a magazine article). You take the zip cord, clip and insulate one wire on one end, and the other wire on the other end. Put an AC plug on one end and your AM or shortwave radio on the other. It is actually safe. There is no direct electrical connection between the radio and the AC line. The zip cord makes a small valued capacitor (a few pF), so it couples RF but the capacitance is too small to pass any significant 60 cycles (er, Hertz). No danger of electrocution ... unless you construct it wrong or forget to insulate one of the cut ends. (Still, I am sure it wouldn't pass muster by modern electrical standards.)

I recall that it worked, but not better than other antennas. If you were stuck in a small apartment and had no means to run any wire, it might suffice; otherwise it wasn't really worth it.

You can also transmit small amounts of power at lower frequencies into the AC power lines. This is known as "carrier current" and has been used for many decades, first by the utility companies, then by college radio stations, and now in modified form for BPL. In principle the power lines conduct the RF to nearby receivers, but are not meant to actually radiate more than a few yards. As a transmitting antenna, this method is very inefficient and you tend to get a lot of hum (60 Hz intermodulation, esp. from nonlinear loads). But it was the mainstay of unlicensed campus radio stations for much of the 20th century.

The RF doesn't get through the utility step-down transformers. For campus radio, you feed the 120V lines. For BPL, they feed the HV distribution lines.

Andy

Regarding the broken link , I just tryed it and yes it won't work,
funny it was working last night. I have uploaded a copy to the
files section, this one is an older text file but from the same source.

Yahoo group: SkyWires
Date: 2012-06-10 00:32:13 UTC
From: Mark
Topic: 4129 Message: 4138

The loop is constructed from 12ga Copperweld in one continuous length. The connection is made at a CPVC "T" that I made for the purpose with a SO-239 connector on the lower leg and internal wire going from there to the two arms where brass screws make the connections to the ends of the Copperweld wire. Strain relief is maintained via two small stainless steel eye bolts through the end caps of the arms of the "T". The RG-8X coax terminates with a 259 connector screwed on to its female counterpart and sealed with Coax-Seal. On the underside of the CPVC "T", (in the 'armpit' you might say), is a 3/32nd weep hole. The connections to the Copperweld are heavily doped with clear silicone.

We are in a heavy storm cycle down here in Mobile, AL at the moment, complete with serious flooding & frequent lightning. As soon as the weather breaks I'll drop the antenna and give it a good once-over. For my edification, about what SWR should I see on the analyzer?

Thanks!

OK , if I understand the antenna you have a 40M loop , coax fed. If it is fed direct with RG-8X the best you can get is 1.5:1 SWR. A 40M loop to be coax fed needs a 1/4wl electrical length matching section of 72 ohm coax , like RG-59, RG-6 or RG-11 to get a 1.0 to 1 SWR, or you can make a 2:1 balun. If you have a analyzer it is simple to make a matching section, if you don't have one on hand you need to know the velocity factor of you matching section coax to figure the length. A dipole can be close to a 50 ohm antenna, a loop is closer to a 100 ohm antenna so you need the 2:1 balun or a coax matching section.

If you know the type of coax you are going to use I can tell you how long to cut the coax with a tape measure.

If the coax type is unknown cut a section about 20% longer than you think is needed , one end of coax install a PL-259 and attach to your analyzer. Adjust your analyzer until the "X" reading is at zero, the frequency should be about 20% low. Reset your analyzer to the frequency you want and trim your coax to get the "X" back to zero.

As it happens, I do have access to an analyzer through my father-in-law. What is the process?

Thx!

Mark, if you know your coax type and you need a quarter wave section the length is like cutting one side of a dipole except you use 246/ F in MHz times the velocity factor. Radio waves travel slower in the coax dielectric so you multiply your first answer by the number below to get the actual length.

RG213, RG8 solid, RG58 VF is .66
RG6 is .75
RG8X, RG8 foam is .78

Let's say you want 7.2 MHz and have RG-8X, 246/7.2= 34.1666,
34.166/.78=26.650
So your quarter wave is 26.65 feet or 26 ft 8 inches

I hope this helps.

Mark, I've been following this thread for a few posts. I built a 40 meter loop the other day to use for field day. Its in a square and I'm feeding it at the top with rg8x. I pulled it up to about 40 feet off the side of my tower for testing. Its swr is great on 40 and 20 meters and fair on 10. It will load and talk on 15 also. So, if your antenna did work, then it can work again. I'd check the connectors and try a different run of coax. If you use the 1/4 matching stub as proposed it pretty much limits that antenna to your band of choice so I'd fix the current problem before complicating it more. Also, a 1.5 swr is fine hardly any loss @ all (check the line loss tables). As the swr approaches 2to1 some solid state radios start to fold back the output power so I'd watch for that..73 es hope this helps..Alan

Mark , Alan brought up a good point about a matching stub. I also use my loop as multi band, I adjusted the size of my 80M loop for best SWR on 20M. I was just giving you the information on how to build a coax transformer.

Alan, good luck with the loop on field day , it should be a great antenna. I just completed a portable full size 40M vert for field day might even use it on 15 if the band is open.

Thanks, that semi vertical loop worked real well when I tested it..Need more vertical here to work back east where there are more hams..not many here in montana...Yes, the article called for ladderline, but I tried the coax feed and was really surprised...Mark, hope you figure that loop problem out..just use process of elimination and should find it...73, alan

Problem Solved!

Once the weather cleared & I had the time, I dropped the wire and checked every foot. Then I disassembled the feed point.

BINGO!

One connection was corroded completely through! Looked fine coved in the sealant, but somehow our tropical climate got to it despite my efforts. Guess I'll have to set up semi-annual inspections!

Once repaired and hauled into position it ran like a top.

Thanks, guys!

I am a race car engineer, and I can say for sure that if the silicone sealant you used smelled of vinegar (acetic acid) it's terrible stuff around electronics. the acetic acid starts a corrosion process off like crazy from the moment it's applied. In automotive usage it has another further nasty side effect, and used in quantity it can "kill" O2 sensors. If you use a silicone type sealant be SURE it is suitable for use on bare electronic connections. VERY generally speaking if it does NOT smell of vinegar you are in with a chance. if it DOES smell of vinegar.... well you know what can happen perhaps? Good luck 2E0ILY England.

Go in a "pet shop" and ask for aquarium sealant

That is neutral (does not smell like vinegar)

Dg9bfc

Sigi

Ps if you have a ladderline fed loop you can easy check weekly if everything
is ok with an ohm-metre (dvm)

Silicone sealants don't belong around technology.

For sealing outdoor connections, find some self-vulcanizing tape. This is offered in Big Box Home supply stores as "rubber splicing tape". Typically UL listed for 600 volts outdoors and underground.

There's no adhesive to this tape. You stretch it out to about double its relaxed length, then wrap over and over. The stuff sticks to itself, and after a few days of hot/cold, it "melts" into itself, forming an amorphous, and VERY well sealed rubber mass. It is under a lot of tension, even once "set", so you want to protect it with ordinary vinyl electrical tape.

To remove it, unwrap the vinyl electrical tape, then make just one knife cut on the rubber, and it snaps off, because it's still under tension.

Friend of mine on the Georgia coast says his connections, 15 years later, looked like new when he exposed them.

Hi All,

The self vulcanizing tape is by far preferable to silicone sealants.

That said, if you have to use silicone, the ones to go for are marketed as
☐neutral cure☐ sealants and to not have the vinegar smell as they cure.

4156. Voltage breakdown

Yahoo group: SkyWires
Date: 2012-09-20 17:38:17 UTC
From: Richard Schmuke
Topic: 4156 Message: 4156

Ok I gots a question for all you educated people out there. I am curious on the voltage is required to jump a .090 gap in about 50% humidity. The reason I ask is because last night my balun was arcing onto the top of my tuner. It would fire about every 5 to 7 seconds. My balun is mounted on a Lexan sheet and the 5 way binding post at the antenna end has a .090 gap above the surface it is sitting on. I don't need the capacitor plate numbers from the ARRL handbook because that is for a tank circuit that has a flywheel effect. The coax from the balun to the tuner was disconcerted but the doublet antenna was connected. I plugged a test lead into the 5 way post and the other end to my ground run to stop the arcing but I am wondering how high the voltage was.

Here is a picture of the balun and 5-way post,

http://i1102.photobucket.com/albums/g453/KD0ZZ/EndView-1.jpg

Rich , Kd0zz

Looking at charts too long and you will get analysis paralysis

I assume you are talking about static discharge?

I would go with the Handbook figures. .090 isn't much gap, I've seen quarter inch arcs at a big knife switch just from snow flakes landing on the antenna.

From: klauber.alex
Topic: 4162 Message: 4162

Australia ☐ Radio Australia on 9580 in English at 0115.Male announcer hosting a magazine show. (Klauber,NY)

Thailand- Radio Liberty on 15530 inTelugu. Male announcer with regional music. (Klauber,NY)

Singapore ☐ BBC on 11945 in Burmese at 0147. Male host conducting telephone interviews. (Klauber,NY)

Saudi Arabia ☐ Radio Riyadh in Arabic on 15435 at 1619. Male host conducting phone interviews. (Klauber,NY)

India ☐ All India Radio in Arabic on 13640.Male announcer at 1758. (Klauber,NY)
AIR on 13695 in English to Africa at 1804. Female announcer with the news. Indigenous music at 1820. (Klauber,NY)
AIR on 11670 with a musical program at 1915 in English. (Klauber, NY)

Iran ☐ V.O. Islamic Republic of Iran on 11980 to Europe in German at 1813. Female announcer with what appears to be the news. (Klauber, NY)
V.O. Islamic Republic of Iran on 12080 in Arabic with musical program at 2312. (Klauber, NY)

Madagascar ☐ Radio Japan on 15720 in English at 1820. Male and female hosts with a musical broadcast. (Klauber, NY)

Moldova ☐ Radio Pridnestrovye in English at 1840 on 9665. Male announcer. (Klauber, NY)

Germany ☐ Family Radio on 1375 at 1846 in English. Male host, however there is much noise and low audio. (Klauber,NY)

Angola ☐ Voice of America English on 12015 with an editorial on the Presidential debate of 10/03/2012 read by a female announcer. Signed off at 1900. (Klauber, NY)

Botswana ☐ Voice of America on15580 in English. Editorial at 1856 read by a female announcer. English service continued after 1900 with the news. (Klauber, NY)

Russia- Voice of Russia on 12040 in English at 2045. Male and female announcers with Russian sports. (Klauber, NY)

Romania ☐ Radio Romania in English on 11880 at 2052 with details about their "Salt Mines" contest. End of English service at 2055. Male host. (Klauber, NY)

Nigeria ☐ Voice of Nigeria with singing on 7255 at 2155 in Fulfulde. Sounds like tribal singing. Very strong signal and audio with modest fading. Station ID at 2200. (Klauber,NY)

China ☐ CRI on 11620 at 2338 in Vietnamese with a musical program hosted by a female announcer. (Klauber, NY)

Albania - CRI on 9570 and 6020 in English at 0150. Female interviewing a male about religious faith in China. (Klauber, NY)

Spain - Radio Espania De Exterior on 9535 at 0205 with the news read by a male announcer in Spanish. (Klauber, NY)

Alex Klauber
Receiver: Sangean 909
MFJ 1045C Preselector
Antenna: 200' long wire antenna

Hi,

I need to invest in a pair of Lineman Pliers to make wire antenna work easier. What do you recommend? I'm looking at Klein brand tools.

Tnx,

Mike KA2FIR

It all depends on what the wire is you are working with.

I always thought Klein and "lineman's pliers" were synonymous, I always called them "Klein pliers" ;-)

As for suitability, that depends on what you are using for antenna wire. I have some antenna wire here that need more than lineman's pliers (three strand #12 copperweld). Farm fence pliers work better for heavy gage wire and are inexpensive. OTOH, for typical antenna wire, any good pair of cutters will do fine.

Klein is very good brand and you cant go wrong with them. There are many other brands also but stay away from some that are "too good" of a price. I would also look at craftsman. Remember you are coming up on black Friday. I got a auto ranging DMV that covers caps and frequency for half price two years ago at the sale.
http://community.craftsman.com/Craftsman-Digital-Mini-Multimeter-reviews?tab=details

At $15.95 I could not say no., normal price $31.99

Also note, if you get into copperweld antenna wire be careful of using tools made to cut copper wire. I use a pair of pliers for safety wire when cutting copperweld antenna wire. I got a roll of RG-11 size CCTV cable and it has 14ga coperweld in the center. Makes great long antennas but can nick a copper cutting tool.

Hi,

I'm looking for pliers for cutting and making splices. I usually work with 14ga stranded bare or insulated but I do have some scraps fo 12ga solid insulated that I'd like to try splicing together and I think I'll need a good pair to do that.

Tnx,

Mike

I have a very old pair of Klein's still in good shape. Also a couple pair of Craftsman and several cheap China ones, I don't mind nicking the China ones.

4174. Tuner question

Yahoo group: SkyWires
Date: 2012-11-20 23:26:34 UTC
From: Jerry Allen
Topic: 4174 Message: 4174

I am new to the group and am happy to see that such a group exists. I have homebrewed many different wire antennas, but never before have I built a Loop Skywire. I am putting up an 80M version (68 ft. to each of 4 sides) at 40 ft. up, and I will be feeding it with 450 Ohm ladder line and using it as a multibander. My tuner will be my trusty MFG 941E aka Versa Tuner II which has the built in 4 to 1 balun for using balanced line. My question is, is this tuner adequate for tuning the Skywire? I don't plan on exceeding the tuner's 300 Watt limit. I just want to know if this tuner will help the Skywire live up to it's fine reputation.

As I recall, one of the fellows near me uses one of the models of the MFJ Versatuner with his 75/80m loop and 450ohm window line. He swears by it.

I'll be using a the MFJ-941C I've got with mine, once I get it up.

The loop and tuner will work and do a job good enough for the radio to work . I later moved up from a MFJ-941E to a 962D. It has a roller inductor but I could not get the SWR all the way to 1:1. I had to remake the balun to get the SWR perfect. I do love my loop it is my main antenna for most bands, even up to 6M.

How much 450 lsdder line should I use for a 80 meter loop for all bands? My turner will be mannual.
I also want to go from barefoot to 1000 watts what guage wire is recommended?

From: Dr.Ace Ratliff
Topic: 4178 Message: 4179

Hello,

Keep the feedline around these lengths.

[The WORST POSSIBLE line lengths are shown in brackets]

160 meter antenna 35-60, 170-195 or 210-235 feet
[Avoid 130, 260 ft]

80 meter antenna 34-40, 90-102 or 160-172 feet
[Avoid 66, 135, 190 ft]

40 meter antenna 42-52, 73-83, 112-123 or 145-155 feet
[Avoid 32, 64, 96, 128 ft]

Some slight trimming or adding of feedline may be necessary to accommodate
the higher frequency bands.

I use 14 guage wire but 16 guage should be fine too.

73, Ace

There is an interaction with the feed line when the feed line is close to resonance (this happens at several lengths for the same frequency). So we try to avoid these lengths. To work most bands 110ft seems to work well for me.

What exactly interacts with what??

Blindly avoiding several lengths (perhaps because there might be
issues, say with guy wires or in certain specific situations) seems
silly if you don't understand why they are being avoided.

Where exactly is the problem with those lengths of feedline?

Is it the feedline interacting with the near-field and acting as a
reflector to the radiator? Easy to avoid ... run the feedline away
from the antenna, not parallel to it.

Is it because the impedance on the feedline goes to a funny value? It
can't be that. Whole multiples of a half wavelength are being
discarded as unsuitable ... when those are perhaps some of the more
desirable choices to use (they reflect the antenna's impedance at the
tuner's end, rather than transforming it into something off the charts
with an impossible-to-match SWR).

Andy

Hi Andy,

These lengths to be avoided are to do with the impedance they would present at the tuner/rig side of the transmission line versus the impedance the antenna presents to the transmission line at the antenna end. When there is a mismatch between the antenna impedance and that of the transmission line, the impedance along the line varies considerably as a function of the length of the transmission line in terms of wavelength and the velocity factor of the transmission line.

For your purposes, the velocity factor of 450 Ohm transmission line is essentially 1, so we can leave this variable out of the explanation.

For example, a 1 wavelength 80mtr resonant loop in a real world installation might present an impedance of say 110 Ohms which you are then feeding with 450 Ohm balanced line. The issue of transmission line lengths is not a problem from an impedance matching perspective when there is an exact match between the antenna feedpoint and the impedance of the transmission line. In that case, we just consider the line loss as a function of length of the transmission line. (example ¼ wavelength elevated vertical with sloping radials fed with a random length of 50Ohm coax).

So because we have a mismatch between the loop□s feedpoint impedance and the impedance of our feedline, we need to factor in the length of feedline (as explained below) to avoid impedance matching issues at the tuner/rig side of the feedline.

ANTENNA FEEDPOINT IMPEDANCE FOR A CLOSED LOOP (SKYWIRE) :

- Low(ish) - When antenna is an even multiple of ½ wavelength at operating frequency. (ie Full wavelength loops)

- High - When antenna is an odd multiple of ½ wavelength at operating frequency (ie .5 , 1.5 , 2.5 wavelength loops)

The impedance presented to the rig/tuner is a function of both the antenna feedpoint impedance and the length of transmission line used.

TRANSMISSION LINE LENGTHS :

There are 2 special case lengths re transmission lines:

- ½ wavelength (or multiples of) at frequency of operation. These lengths will present to the tuner/rig the same impedance that was present at the antenna feedpoint.

- ¼ wavelength (odd multiples of) at frequency of operation. These lengths will at as □impedance transformers□. If there is a high impedance at the antenna feedpoint, a ¼ wavelength transmission line will present a much lower impedance to the tuner/rig. If there is a low impedance at the antenna feedpoint, a ¼ wavelength transmission line will present a much higher impedance to the tuner/rig.

The lengths to be avoided as I understand it are odd ¼ wavelength multiples at the frequency of operation as these lengths will convert the low(ish) impedance at the closed loop antenna feedpoint to much higher impedance at the tuner/rig side. Higher impedances are harder to match at the tuner/rig side and hence we try to avoid creating situations with certain lengths of transmission lines that are very likely to present difficult to match impedances.

I□m sure there is a better technical explanation than this, but hopefully, this will get the concepts across.

73,

Michael

A current fed antenna (halfwave dipole or 3/2 waves etc) and a quarterwave
line .... or a fullwave antenna and a quarterwave line

Both will produce a very high impedance on the shack end

For a multiband use (and that is the reason to use ladderline) and for easy
matching and low losses we try to avoid very high and very low impedances

Very low impedance means high currents (so maybe higher loss)

Very high impedance means high voltage (and maybe tuner would arc over)

Hope now it is clear why in different setups different length of dipole or loop and length of ladderline interact ...

Yup, I got that one.

But this was a loop (OK, not a huge difference, though depending on its size), and the whole multiples of 1/2-wavelength feedline were discarded as unsuitable! Those are the lengths that nearly exactly reflect the antenna feedpoint impedance at the shack end. If the antenna's feedpoint impedance was workable, then that length of feedline ought to be just fine. In fact, perfect.

So why avoid it? Just because someone says the length is "resonant"?

It reminds me of the saying ... the blind leading the blind.

I would probably want to avoid using odd multiples of a quarter-wavelength, given that the feedline's characteristic impedance is probably several times that of the loop being fed. That would transform the impedance into something high ... in the kilohms.

But a half-wavelength, and whole multiples? No.

> Hope now it is clear why in different setups different length of dipole or
> loop and length of ladderline interact ...

No, I'm afraid it is not.

Regards anyway,
Andy

Michael,

I get what you're saying, and I knew the explanation you gave. It's
something I learned oh, some 40 years ago, in precise mathematical detail,
later followed by the graphical shortcuts (Smith charts).

However, why do we want to *avoid* using half-wavelength long pieces of
feedline??? That's my real question.

*160 meter antenna 35-60, 170-195 or 210-235 feet

>
>
But 64 feet is 1/2 wavelength, and 128 feet is a whole multiple of 1/2
wavelength.

I understand perhaps avoiding the 1/4 wavelength (and odd whole multiples)
when using ladderline, because it will tend to transform the impedance to

something on the other side of 450 ohms such that the geometric mean of it and the antenna impedance works out to 450. What I don't understand is why avoid using the even multiples of 1/4 wavelength too, = 1/2 wavelength and whole multiples thereof?

In fact the target ("desirable") lengths are pretty much guaranteed to put you about a quarter way around on the Smith chart, to where the impedance is significantly reactive, and significantly greater than it is at the antenna (assuming that the antenna itself was close to resonant as cut). Not as large perhaps as it would be if you had gone the full half way around on the Smith chart (i.e., with a 1/4 wavelength piece of feedline), but still significantly greater than the impedance was at the antenna itself. And it gives you a large reactive component that the tuner needs to handle.

Wouldn't it be better to aim for 1/2 wavelength and multiples? I understand that it might be difficult to accomplish on all bands.

Regards,
Andy

Hi Andy,

I understand your specific question now.

I plugged the numbers into a simple spreadsheet and I believe they are telling me that 260ft would present a high impedance match on 20metres as at 14.2Mhz, this amount of feedline is ~3.75 wavelengths. with the .75 (and .25) being the impedance transformation lengths we want to avoid. 17metres would also not be desirable in terms of impedance transformation with this length.

Wavelength of 260ft of Open Wire Feeder on each band

If you are interested, there is free and easy to use loop modelling program called rjeloop4.exe available at the following URL:

http://www.smeter.net/antennas/large-transmitting-loop.php

The link to the program is towards the bottom of the page. NOTE: It runs on WinXP.. will not run on Win7. Not sure about Vista.

The program includes the ability to add the characteristics of the transmission line including its impedance and the length to the model so show you the sort of impedances that will be presented at the tuner/rig side for a specified loop setup.

If you plug the numbers into it for any given loop, you can change the frequency of operation and immediately get a feel for what the impedance matching situation will present for any given frequency of operation.

I think the answers it would give you would be of interest given your question.

73,

Michael

I think some of the issues reflect the limitations of certain tuners. IIRC, Icom says to avoid certain lengths with their AH-4 tuner. OTOH, I'll bet that other, bigger tuners will tune the antenna/feedline without problem. I know my Elecraft K3 internal tuner won't tune my antenna/feedline on a couple of bands but my Palstar AT2K handles it just fine.

A quarter wave section is a transformer. A quarter wave (or odd multiple) can present a low impedance if the antenna is a high impedance. For example, a center fed full wave antenna will have a high impedance but when fed with a quarter wave feedline, it will present a lower impedance at the shack end.

For safety? I would go far far away ... what if the other supports break (insulator or rope)??? And when the wind then blows your antenna on the power lines??? .. you will get a massive fire in your shack ...

What you can do is add additional safety lines that holds the wire up (with some sag) after the normal support came loose

Effect on the antenna (patterns on different bands) ... sure you will have some influence ... but not worth worrying about it I think

I would more worry about NOISE ... and the above safety rules

Antenna modeling can help understand how antennas work.Here is a model of a perfect square 276 foot loop at 15 feet height over moderate ground.It is calculated resonant at 3.594 MHz with 107 ohm impedance.Your difference in measured resonant frequency is due to variations in loop geometry and objects in the near field as well and impedance transformation effects of your transmission line.
[kg6zan_loop_current_ at_resonance] [kg6zan_loop_at_resonance]
Here is the vertical radiation pattern at resonance, the main lobe directed straight up
[kg6zan_loop_pattern_ at_resonance]
At 7 MHz the pattern is still omnidirectional, with a null straight up
[kg6zan_loop_pattern_ at_07MHz]
At 28 MHz the pattern shows many lobes and nulls. It may be deaf for stations in the nulls, but very good for stations just a few degrees away in the lobes.
[kg6zan_loop_pattern_ at_28MHz]
With the free 4nec2 modeling program you can change any of the parameters, terminations, etc. and observe the expected effect on performance.

4202. Backyard Wire Loop Antenna, Baluns and Tuning

Yahoo group: SkyWires
Date: 2013-02-07 03:00:53 UTC
From: Noodle10536
Topic: 4202 Message: 4202

Hello evryone, I have installed a 545' wire loop antenna. It is in a diamond shape due to available trees to support it. I would describe the shape similar to the ARRL symbol (diamond). It is fed off one of the ends to about 40' of 16ga 450 ohm ladder line into the shack. The loop varies in height from about 25' at the low point to about 38' at the high point. I have experimented with many baluns but thus far have not gottne it to tune easily and difficult to tune on 160m. I have tried two 4:1 baluns, a 9:1 balun and a 1:1 balun. I have tested it with an MFJ analyzer and have gotten about 7 ohms at 1.900 with the 9:1 and 4:1 and about 200 ohms with the 1:1. Any suggestions to improve ease of tuning welcome.

Thanks, Peter.

On my topband loop i also changed the feeder length to have a low swr

Now the end result is that on some bands I use the short feeder (from antenna to shack) and on some bands I add another length (plugged in between with banana plugs)

I made it easier to tune on one of my antenna set ups by adding switchable balun, I use 1:1 on 160 and 4:1 on other bands. Here is the schematic http://www.angelfire.com/electronic2/qrp/balun.html ,it is for QRP, I just used larger components for a KW size.

4209. Large vertical loops

Yahoo group: SkyWires
Date: 2013-03-18 00:23:44 UTC
From: Brian Burns
Topic: 4209 Message: 4209

Hello All,

I've got space to put up a vertical skywire, but not a horizontal one. I'm thinking of a vertical rectangle that is 140 feet long by 34 feet high with the top horizontal at 43 feet and the bottom one at 9 feet. Unfortunately my interests include the WARC bands, 30m, 17m, and 12m, as well as the usual harmonically related ones, 80m through 10m.

It would seem that a long enough matching stub, with shorting bar, attached to the loop at some point would allow it to be adjusted to a reasonable SWR on any band. I don't mind going outside to move the shorting bar when I want to change bands.

Another possibility would be to put up two concentric loops of quite different sizes, but I can't find any info on the web by anyone who has done that except in cubical quads.

I'm thinking of feeding with 600 ohm ladder line, but am open to suggestion on that, as well as the best feed point. I have an old Harvey Wells Z-Match antenna tuner that likes to work with open wire feedline, and a Kenwood that wants to look at coax.

Whaddya think?

Cheers,

Brian Burns Ex: W5BRO, K6UCD

Use 450 ohm twin lead to feed the loop and a tuner on the transmitter end and I guarantee you'll work the world. I have done the same thing between two towers and in the first year I worked more than 70 countries on 80 meters, and a bunch more on the est of the bands, including the WAC bands. The direction of radiation will be at right angles to the loop. You'll have great success.

Good luck!!

Dave, W8QW

4211. RE: [SkyWires] Large vertical loops

Yahoo group: SkyWires
Date: 2013-03-18 15:11:44 UTC
From: Brian Burns
Topic: 4209 Message: 4211
Attachments: 1 described; binary payloads are missing from this source WARC

Hello Dave,

Thanks very much for the encouragement! I didn’t mention that I’m interested in QRP, so running only 5 watts, I can’t afford to have much in the way of losses in the system. My antenna tuner will certainly do a good job of matching my transmitter to the feedline—they ought to be called feedline tuners (;->)…

It’s matching the feedline impedance to the antenna impedance at the antenna’s feedpoint on all these oddball frequencies that concerns me.

So, I’m still wondering whether it would work to put up concentric loops of different sizes to get better matches of the feedline to the antenna on the different bands. Or, whether adjustable length matching stubs could be used to change the electrical size of the loop to bring it to resonance on the various bands.

Cheers,

Brian Burns

I want to build a loop - 80M or 160. For multi-band. I can run ladder line most of the way, but have about 20 feet inside the house. I'd like to run dual-coax from next to the house to the operating position and tuner. What do you recommend between the "balanced" coax (dual), or just a balun and coax to the ladder line? Maybe a 1:9?

Always had dipoles but this lot is not set up for those. The feedpoint will be in the middle of the yard and as of now, no towers :-(

I also have an Alinco Auto tuner for random wire that I can use. Ground the control line and it will tune. I could locate it outside, maybe with a balun. I'll check the "tuning range".

Thanks,
Bill

I'm not sure what a "superloop" is unless the inference is that loops are "super" in general, but I've used a full wave loop for years and am very pleased with it. Mine is an 80m loop but the principles are the same. If you intend to use it as a mono band antenna the you can feed it with coax directly, but if you plan on using it as a multi band antenna make it a little shorter, use a good quality 4:1 balun and your internal tuner will be able to match it as expected. The reason it needs to be a bit shorter on the lowest band is the impeadance needs to NOT be right at 50ohms since you're using it on other bands where the impeadance will surely be different. This way the balun and the tuner do the heavy lifting. Open ladder line can be used instead of the above but refer to the ARRL Antenna books or other sources. There's a lot of incomplete and just wrong information on ths web so stick with good sources. I use a DX Egineering "tuner" balun after many orher failed methods. They have an EXCELLENT faq page that hits this nail on the head.

Good luck,
Glen -KE7FD

I think they added the wording "super" for the same reason you said Glen, mine also worked super. I put one up with a coax transformer section and it worked fine. I wanted a little more and other bands so now use a 80M delta loop with a homemade 4:1 balun at the feed point and work all bands 40 thru 6 with it. It is my main antenna.

Here: http://www.radioworks.com/csl40.html

Or the 80m version: http://www.radioworks.com/csuperlo.html

There are plans all over the Internet for building your own.

Even W8JI has something to say about it:
http://www.w8ji.com/super%20miniloop.htm

Not really a Skywire because they usually hang vertically.

Andy

Interesting. Not tried a delta as I need 80m.

From: Richard Schmuke
Topic: 4213 Message: 4220
Attachments: 2 described; binary payloads are missing from this source WARC

When I build something I build per SWAG on most things. This is my main antenna. I put up a 80M size delta loop, installed split bolt and adjusted.

Feed point about 35 to 40ft the other two about 25 to 30ft.

Feed point on the south because that is where the support is.

I cut it approximately, I put stakes in the ground, layout the wire and hoisted it up

Hooked up the analyzer and tweaked it for the middle of the 20M phone band, The theory for size is as follows and you can see my SWR readings are at my bucket.

http://s1102.photobucket.com/user/KD0ZZ/media/80MLoop_zpsa6e4cfe7.jpeg.html

All my main bands are good but 17M comes in a little low on phone but with a any type of tuner you have a all band antenna, I even work 6M on it

Richard,

Wow - that sounds great!

I probably just have room to put up a shape like this and this size. While I will use a tuner when necessary, I want to get away from it for "all" the time. My youngest is 12, with his General. We need more antennas!

Thanks,
Bill

Bill when you sent a copy my email back it did not have the size chart, because I can't see my email thru yahoo I have to ask did the chart showing the 2x,3x.4x and so forth come thru????

For more antennas I have a 160 doublet with a 80M fan element that is a killer on 10M to the east and west, the loop is better north and south. I also have a 40M thru 6M all band vertical in work.

Thank You Richard!

Yes - it did. I have been looking at that chart. I do not think I have room for the 566' loop - even if I squiggle it around... Too bad because they are all even multipliers. I see how the chart works. Sure would be nice if they all fell into evens, at least 40, 20 and 15M.

That it is resonant at the even multiples is interesting. From your SWR table the readings aren't too bad on the odd multiples. I will look at our mounting options. I have a LOT of wire - probably about 16 AWG with insulation. Tinned wire, makes great antennas. Since it is insulated I wonder what effect would be from running it through the Leyand Cyprus branches? That would be a great way to string it up on 1 side... Wishing I had planted some of those on the other side of the yard, now!

I want a good NVIS antanna for 80 and maybe 60 and 40M. Also want one for lower angle for DX. Cannot use the front yard, unfortunately.

Your projects look very nicely done.

Thanks,
Bill

Hello Rich,
The length on the drawing comes out to 3.55 MHz if you use the formula.
I am interested in a couple of things about this antenna:

1. Where is it directional? I'm thinking out of the V at the feedpoint. Mine would be looking out to the North.

2. How high did you have it? I could put the feedpoint at about 20 to 25 feet, higher on the "back".

3. Is it a close match on any bands?

(Have not plugged it into EXNEC but if I get a chance I want to). Will share the results.

Tnx and 73,
Bill AJ4TX

OK Bill now the rest of the story. I told you the good here is the bad. A couple of years ago we were going to have a bad snow/ice storm so being a good keeper of antennas I went out and dropped mine to the ground. The ice broke a lot of tree limbs a few days later I pulled the wires out of 18" of snow and ice back up, I no longer had a good triangle due to down supports but what the heck. I no longer had good SWR, went back out and reset to a eyeball triangle, back to good SWR. My 80M size delta worked great so why not double it. I made sort of a out of shape rectangle, I could not get the bands to come it with my supports without going into the scrub oak trees. I went back to my 80M delta shape , adjusted to a multiple of the 20M band and still there.

Thank You Richard!

Yes - it did. I have been looking at that chart. I do not think I have room for the 566' loop - even if I squiggle it around... Too bad because they are all even multipliers. I see how the chart works. Sure would be nice if they all fell into evens, at least 40, 20 and 15M.

That it is resonant at the even multiples is interesting. From your SWR table the readings aren't too bad on the odd multiples. I will look at our mounting options. I have a LOT of wire - probably about 16 AWG with insulation. Tinned wire, makes great antennas. Since it is insulated I wonder what effect would be from running it through the Leyand Cyprus branches? That would be a great way to string it up on 1 side... Wishing I had planted some of those on the other side of the yard, now!

I want a good NVIS antanna for 80 and maybe 60 and 40M. Also want one for lower angle for DX. Cannot use the front yard, unfortunately.

Your projects look very nicely done.

From: Bill Allen
Topic: 4213 Message: 4225

Uh-oh - the rest of the story!
(now old Paul Harvey stories are flashing through my head!).

Hmmm - sounds like the shape has a lot to do with the performance. Not surprising. Actually this loop is the first time I have heard of resonance on multiples like that (at least that good!). After this information, it would be interesting to model - see if it follows life, so to speak. I expected resonance where cut, and maybe tuner-friendly harmonics. Al, N4ALO talks about his loop - I think he used a 4/3 or 5/4 loop at 80M. Cut for ~2.5 MHz or something like that. I'll have to review. But still using a tuner, as I recall. (He is on 40M a lot, and I generally have 40M going in the car.

Well, again the good: I have a feedpoint location in back of the house and can get a pretty good triangle out the back. Favoring North is OK - if it is low enough it'll go over the pole and I love talking to Eastern Europe, and if not, it will probably talk to Tennessee where I have other friends.

Other antennas are a longwire that needs to be replaced (with a loop?) and a Cushcraft that I inherited and am in the middle of cleaning up the connections on the matching network.I may stick it out back in the back, and feed it with ladder line and a couple of baluns, or something. Depends on resonance, if it even works, etc. Not going to bury a lot of radials, but they say to put it 8' above the ground. It came off the top of an 80' tower. Sorry, I don't get a tower :-(even though i have 3 sections sitting on the ground.

-Bill

Hello Rich,
The length on the drawing comes out to 3.55 MHz if you use the formula. I am interested in a couple of things about this antenna:

1. Where is it directional? I'm thinking out of the V at the feedpoint. Mine would be looking out to the North.

2. How high did you have it? I could put the feedpoint at about 20 to 25 feet, higher on the "back".

3. Is it a close match on any bands?

(Have not plugged it into EXNEC but if I get a chance I want to). Will share the results.

Tnx and 73,
Bill AJ4TX

4226. Introducing me to the group

Yahoo group: SkyWires
Date: 2013-04-26 15:19:27 UTC
From: pu2clr
Topic: 4226 Message: 4226

Hello everybody,

My name is Ricardo, PU2CLR, and I am new as amateur.
I have interesting in Loop Antenna and I am looking for a way to work on 80 meters with a kind of loop.

For while I have a Yaesu Ft817-ND and I have had more success working on 10 meters with a homebrew magnetic loop antenna.

I have experimented some approach to control my Loop Magnetic Antenna remotely with Android device, IR and Arduino.

If anyone has interest in this kind of control, I posted some videos on YouTube (see links below). Also, these projects are available on Github repository (https://github.com/pu2clr).

Automatic Antenna Tuner for QRP controlled by Android and Arduino - Part 2:
https://www.youtube.com/watch?v=cZjbZRGTyVc
Arduino, IR and Encoder controlling Magnetic Loop Antenna Tuner:
https://www.youtube.com/watch?v=zD-wKD19_8U
QSO with Magnetic Loop Antenna: https://www.youtube.com/edit?video_id=ylhLfB0XhZU&ns=1
Automatic Antenna Tuner for QRP with Android and Arduino - Part 1:
https://www.youtube.com/watch?v=55bQ9xVWzuM

I posted others videos showing QSO and tests on my youtube channel.

Thanks for the welcome to the group.

73.
PU2CLR,
Ricardo.

4227. Support for 160m loop?

Yahoo group: SkyWires
Date: 2013-04-26 15:58:40 UTC
From: O-B-1
Topic: 4227 Message: 4227

What is an economical way to support the loop?

My property is 150x704 feet, has a flat area about 100 feet from house 150x500 feet that has no trees whatsoever.

It appears wood utility poles are fairly expensive.

The width of the property at 150' leaves hardly any room for guy wires if the sides of the loop are 143.5 feet.

Ideal height is 40 feet I understand.

Any ideas?

Subject: RE: [SkyWires] Re: superloop 40m aerial

Uh-oh - the rest of the story!

(now old Paul Harvey stories are flashing through my head!).

Hmmm - sounds like the shape has a lot to do with the performance. Not surprising. Actually this loop is the first time I have heard of resonance on multiples like that (at least that good!). After this information, it would be interesting to model - see if it follows life, so to speak. I expected resonance where cut, and maybe tuner-friendly harmonics. Al, N4ALO talks about his loop - I think he used a 4/3 or 5/4 loop at 80M. Cut for ~2.5 MHz or something like that. I'll have to review. But still using a tuner, as I recall. (He is on 40M a lot, and I generally have 40M going in the car.

Well, again the good: I have a feedpoint location in back of the house and can get a pretty good triangle out the back. Favoring North is OK - if it is low enough it'll go over the pole and I love talking to Eastern Europe, and if not, it will probably talk to Tennessee where I have other friends.

Other antennas are a longwire that needs to be replaced (with a loop?) and a Cushcraft that I inherited and am in the middle of cleaning up the connections on the matching network.I may stick it out back in the back, and feed it with ladder line and a couple of baluns, or something. Depends on resonance, if it even works, etc. Not going to bury a lot of radials, but they say to put it 8' above the ground. It came off the top of an 80' tower. Sorry, I don't get a tower :-(even though i have 3 sections sitting on the ground.

OK Bill now the rest of the story. I told you the good here is the bad. A couple of years ago we were going to have a bad snow/ice storm so being a good keeper of antennas I went out and dropped mine to the ground. The ice broke a lot of tree limbs a few days later I pulled the wires out of 18" of snow and ice back up, I no longer had a good triangle due to down supports but what the heck. I no longer had good SWR, went back out and reset to a eyeball triangle, back to good SWR. My 80M size delta worked great so why not double it. I made sort of a out of shape rectangle, I could not get the bands to come it with my supports without going into the scrub oak trees. I went back to my 80M delta shape , adjusted to a multiple of the 20M band and still there.

Subject: RE: [SkyWires] Re: superloop 40m aerial

Bill when you sent a copy my email back it did not have the size chart, because I can't see my email thru yahoo I have to ask did the chart showing the 2x,3x.4x and so forth come thru????

For more antennas I have a 160 doublet with a 80M fan element that is a killer on 10M to the east and west, the loop is better north and south. I also have a 40M thru 6M all band vertical in work.

Rich , Kd0zz

To: SkyWires@yahoogroups.com
Subject: RE: [SkyWires] Re: superloop 40m aerial

When I build something I build per SWAG on most things. This is my main antenna. I put up a 80M size delta loop, installed split bolt and adjusted.

Feed point about 35 to 40ft the other two about 25 to 30ft.

Feed point on the south because that is where the support is.

I cut it approximately, I put stakes in the ground, layout the wire and hoisted it up

Hooked up the analyzer and tweaked it for the middle of the 20M phone band, The theory for size is as follows and you can see my SWR readings are at my bucket.

http://s1102.photobucket.com/user/KD0ZZ/media/80MLoop_zpsa6e4cfe7.jpeg.html

All my main bands are good but 17M comes in a little low on phone but with a any type of tuner you have a all band antenna, I even work 6M on it

Hello Rich,
The length on the drawing comes out to 3.55 MHz if you use the formula. I am
interested in a couple of things about this antenna:

1. Where is it directional? I'm thinking out of the V at the feedpoint. Mine
would be looking out to the North.

2. How high did you have it? I could put the feedpoint at about 20 to 25
feet, higher on the "back".

3. Is it a close match on any bands?

(Have not plugged it into EXNEC but if I get a chance I want to). Will share
the results.

Tnx and 73,
Bill AJ4TX

4232. AW: [SkyWires] Support for 160m loop?

Yahoo group: SkyWires
Date: 2013-04-27 00:15:37 UTC
From: siegfried jackstien
Topic: 4227 Message: 4232

No need for a special shape of a loop ... so no need to have equal lengths
on each sides ... (quad works, delta works, hexagon or circle ....) ...

What about fibre glass tent poles (cheap but need some guy lines)

Or wodden "a frame" ???

40feet should be quite easy to erect a loop to (even without trees)

If you use very lightweight wire then also the support can be lighter

My favourite wire for that would be aluminium electric fence wire

VERY light :-)

So with just a slight pull on the ends you have almost no sag even on longer
runs

4233. RE: [SkyWires] Re: Megaloop

Yahoo group: SkyWires
Date: 2013-04-27 03:33:25 UTC
From: Brian Burns
Topic: 4213 Message: 4233

Hello Rich and Bill,

Am I missing something here? I went to the link below, and watched as Callum McCormick drew and analyzed his "megaloop" design. He was being quite enthusiastic about the gain shown by various lobes, but what about all the radiated energy going in other directions? Doesn't that have to be subtracted from the lobe that you happen to be using? I don't doubt that it is an effective antenna, but it seems to me that the gain figures he is quoting would need to be adjusted way down to get a "net gain" figure that is meaningful.

Cheers,

Brian Burns

Bill when you sent a copy my email back it did not have the size chart, because I can't see my email thru yahoo I have to ask did the chart showing the 2x,3x.4x and so forth come thru????

For more antennas I have a 160 doublet with a 80M fan element that is a killer on 10M to the east and west, the loop is better north and south. I also have a 40M thru 6M all band vertical in work.

Richard,

Wow - that sounds great!

I probably just have room to put up a shape like this and this size. While I will use a tuner when necessary, I want to get away from it for "all" the time. My youngest is 12, with his General. We need more antennas!

Thanks,

Bill

Subject: RE: [SkyWires] Re: superloop 40m aerial

When I build something I build per SWAG on most things. This is my main antenna. I put up a 80M size delta loop, installed split bolt and adjusted.

Feed point about 35 to 40ft the other two about 25 to 30ft.

Feed point on the south because that is where the support is.

I cut it approximately, I put stakes in the ground, layout the wire and hoisted it up

Hooked up the analyzer and tweaked it for the middle of the 20M phone band, The theory for size is as follows and you can see my SWR readings are at my bucket.

http://s1102.photobucket.com/user/KD0ZZ/media/80MLoop_zpsa6e4cfe7.jpeg.html

All my main bands are good but 17M comes in a little low on phone but with a any type of tuner you have a all band antenna, I even work 6M on it

Hello Rich,
The length on the drawing comes out to 3.55 MHz if you use the formula. I am interested in a couple of things about this antenna:

1. Where is it directional? I'm thinking out of the V at the feedpoint. Mine would be looking out to the North.

2. How high did you have it? I could put the feedpoint at about 20 to 25 feet, higher on the "back".

3. Is it a close match on any bands?

(Have not plugged it into EXNEC but if I get a chance I want to). Will share the results.

Tnx and 73,
Bill AJ4TX

You don't need to subtract anything. The gain it calculates is the gain of the antenna in that direction.

Every antenna radiates some energy in EVERY direction (except for deep nulls). In each direction there is an energy density, given the power you feed into the antenna. That is what the program calculates.

The total energy density, going out on all the lobes, and all the spaces between the lobes, adds up to no more than the total power you feed into the antenna. It all works out. Really.

Andy

Brian, I do understand you question, I do not understand the computer program well enough to give you an exact answer. I will say it is a good performing wire antenna. It does not out perform my 3 element 15M beam but is much better than any dipoles I have tried at the same time. I have had many types of wire antennas up, and when I extend a wire to get greater gain it will greater nulls. My ladder line fed 160M dipole is great into the far east and Europe on 10M off the ends, dead to Canada and South America but the loop is almost as good on ten to Europe and JA land but also great north and south also. I don't analyze a antenna with a computer but on the air and it works for me.

Rich , Kd0zz

Looking at charts too long and you will get analysis paralysis

Subject: RE: [SkyWires] Re: Megaloop

Hello Rich and Bill,

Am I missing something here? I went to the link below, and watched as Callum McCormick drew and analyzed his "megaloop" design. He was being quite enthusiastic about the gain shown by various lobes, but what about all the radiated energy going in other directions? Doesn't that have to be subtracted from the lobe that you happen to be using? I don't doubt that it is an effective antenna, but it seems to me that the gain figures he is quoting would need to be adjusted way down to get a "net gain" figure that is meaningful.

Cheers,

Brian Burns

Subject: RE: [SkyWires] Re: superloop 40m aerial

Uh-oh - the rest of the story!

(now old Paul Harvey stories are flashing through my head!).

Hmmm - sounds like the shape has a lot to do with the performance. Not surprising. Actually this loop is the first time I have heard of resonance on multiples like that (at least that good!). After this information, it would be interesting to model - see if it follows life, so to speak. I expected resonance where cut, and maybe tuner-friendly harmonics. Al, N4ALO talks about his loop - I think he used a 4/3 or 5/4 loop at 80M. Cut for ~2.5 MHz or something like that. I'll have to review. But still using a tuner, as I recall. (He is on 40M a lot, and I generally have 40M going in the car.

Well, again the good: I have a feedpoint location in back of the house and can get a pretty good triangle out the back. Favoring North is OK - if it is low enough it'll go over the pole and I love talking to Eastern Europe, and if not, it will probably talk to Tennessee where I have other friends.

Other antennas are a longwire that needs to be replaced (with a loop?) and a Cushcraft that I inherited and am in the middle of cleaning up the connections on the matching network.I may stick it out back in the back, and feed it with ladder line and a couple of baluns, or something. Depends on resonance, if it even works, etc. Not going to bury a lot of radials, but they say to put it 8' above the ground. It came off the top of an 80' tower. Sorry, I don't get a tower :-(even though i have 3 sections sitting on the ground.

-Bill

OK Bill now the rest of the story. I told you the good here is the bad. A couple of years ago we were going to have a bad snow/ice storm so being a good keeper of antennas I went out and dropped mine to the ground. The ice broke a lot of tree limbs a few days later I pulled the wires out of 18" of snow and ice back up, I no longer had a good triangle due to down supports but what the heck. I no longer had good SWR, went back out and reset to a eyeball triangle, back to good SWR. My 80M size delta worked great so why not double it. I made sort of a out of shape rectangle, I could not get the bands to come it with my supports without going into the scrub oak trees. I went back to my 80M delta shape , adjusted to a multiple of the 20M band and

still there.

Thank You Richard!

Yes - it did. I have been looking at that chart. I do not think I have room for the 566' loop - even if I squiggle it around... Too bad because they are all even multipliers. I see how the chart works. Sure would be nice if they all fell into evens, at least 40, 20 and 15M.

That it is resonant at the even multiples is interesting. From your SWR table the readings aren't too bad on the odd multiples. I will look at our mounting options. I have a LOT of wire - probably about 16 AWG with insulation. Tinned wire, makes great antennas. Since it is insulated I wonder what effect would be from running it through the Leyand Cyprus branches? That would be a great way to string it up on 1 side... Wishing I had planted some of those on the other side of the yard, now!

I want a good NVIS antanna for 80 and maybe 60 and 40M. Also want one for lower angle for DX. Cannot use the front yard, unfortunately.

Your projects look very nicely done.

Thanks,

Bill

Brian,
I see the issue - and actually kind of like the multi-lobed pattern. The main "gain" - pun intended - may be because of the lower angle of radiation. It is shooting out in a saucer-shape with different little nulls, and very attenuated in the azimuth, except for 80 or 160M.

So it does not have the great F/B ratios but makes up for it in simplicity and angle of radiation.

That's my $0.02 until I build it! Or model it in EZNEC.
Let's build them - too simple NOT to!
73,
Bill AJ4TX

4238. Re: Megaloop

Yahoo group: SkyWires
Date: 2013-04-29 00:23:34 UTC
From: B
Topic: 4213 Message: 4238

Ya know, I read these posts about all the extravagant antenna arrays that everyone is building and think back to when I was small and my Dad was a Ham Radio operator who just loved QRP. I remember I helped him string an 80' long wire from the corner of the roof to a telephone pole in the neighbors yard. He fed it to the "shack" with some RG58 with the shield to a ground rod next to the house. He would be in the "shack" all night long on Friday and Saturday nights working 40 and 80 meters , CW ALL OVER THE WORLD. The only tuning he did was the tank circuit in the homebrew transmitter he used. A homemade antenna switch between the transmitter and the old Hallicrafters receiver he used. No more than 3 or 4 watts input.

Now that was Ham Radio at it's best. I still have some of his cards that he received from his "accomplishments"!!! I was 6 at the time so that made it 54 years ago.

4239. Re: [SkyWires] Re: Megaloop

Yahoo group: SkyWires
Date: 2013-04-29 00:31:06 UTC
From: Dave Leisman
Topic: 4213 Message: 4239

Ya know you are absolutely right. With all the amplifiers and sophisticated micro processor circuitry I wonder if we have lost the "ham" in amateur radio. How many can put together or even draw a Colpits oscillator anymore? Not to indict because I know everything has to move forward, but at what expense?

I'll take a qrp rig and wire antenna who works 100 countries over the spohisticated transceover, a "megawatt" amplifier with stacked arrays who works 150 countries in a year, any day.

4240. Re: Megaloop

Yahoo group: SkyWires
Date: 2013-04-30 01:24:18 UTC
From: B
Topic: 4213 Message: 4240

Anyone can go out and buy $4000 worth of equipment ,and get all over the universe but to build a 3 or 4 watt transmitter yourself and making that first contact is the real thrill of Ham Radio. I know guys that have built their way up to a 100 watts over years of hamming. But it was always the thrill of doing it oneself that made it wotrh while. I have been a guitar player for over 40 years, The absolutely best amplifier is the 40 watt tube type that I built myself--35 years ago and still using it.!!!!

--- In SkyWires@yahoogroups.com, Dave Leisman <w8qwdave@...> wrote:
>
> Ya know you are absolutely right. With all the amplifiers and sophisticated micro processor circuitry I wonder if we have lost the "ham" in amateur radio. How many can put together or even draw a Colpits oscillator anymore? Not to indict because I know everything has to move forward, but at what expense?
>
> I'll take a qrp rig and wire antenna who works 100 countries over the spohisticated transceover, a "megawatt" amplifier with stacked arrays who works 150 countries in a year, any day.

From: raymond mitchell
Topic: 4213 Message: 4241

A full size ant helps ya keep in touch with friends and family. Sometimes 10W to 40W will do fine, many times it will not. Other times when folks say the band is dead ya need 1000W or better for reliable communications. During Ike and Catrina the radio provided the only reliable communications. Many times 100W was fine, most of the time 500W or so was fine, but it was rare when 1000W+ could not get through. The antenna is the most important part of our system. Still a good cloudburner, while hooked to that antenna, has proved useful.

Anyone can go out and buy $4000 worth of equipment ,and get all over the universe but to build a 3 or 4 watt transmitter yourself and making that first contact is the real thrill of Ham Radio. I know guys that have built their way up to a 100 watts over years of hamming. But it was always the thrill of doing it oneself that made it wotrh while. I have been a guitar player for over 40 years, The absolutely best amplifier is the 40 watt tube type that I built myself--35 years ago and still using it.!!!!

--- In SkyWires@yahoogroups.com, Dave Leisman <w8qwdave@...> wrote:

>

> Ya know you are absolutely right. With all the amplifiers and sophisticated micro processor circuitry I wonder if we have lost the "ham" in amateur radio. How many can put together or even draw a Colpits oscillator anymore? Not to indict because I know everything has to move forward, but at what expense?

>

> I'll take a qrp rig and wire antenna who works 100 countries over the spohisticated transceover, a "megawatt" amplifier with stacked arrays who works 150 countries in a year, any day.

4242. Re: Megaloop

Yahoo group: SkyWires
Date: 2013-04-30 23:26:48 UTC
From: B
Topic: 4213 Message: 4242

There really is not such a thing as a "full size" antenna. The efficiency of an antenna and paying attention to wave propagation and atmospheric conditions is. And I am also not referring to ham radio operators that are gearing themselves for emergency communications. Cb Radio has proven itself to be reliable local emergency communications. I am referring to the purebred"Ham" that is interested in the hobby aspects of Amateur Radio. Myself and myself were never into "pegging" someone meter. We were interested in making contact using homebrew and very low power transmitters. Dad used a "Goonie Bird" for years on 2 Meters and we had some impressive contacts using a simple beam with 7 watts input. And we were also part of the Local ARRL Air Force Civil Defense network here in lower NY State. If anyone reads the ARRL Ham Radio handbook, it suggests to start out small.

>
> A full size ant helps ya keep in touch with friends and family. Sometimes 10W to 40W will do fine, many times it will not. Other times when folks say the band is dead ya need 1000W or better for reliable communications. During Ike and Catrina the radio provided the only reliable communications. Many times 100W was fine, most of the time 500W or so was fine, but it was rare when 1000W+ could not get through. The antenna is the most important part of our system. Still a good cloudburner, while hooked to that antenna, has proved useful.

> Anyone can go out and buy $4000 worth of equipment ,and get all over the universe but to build a 3 or 4 watt transmitter yourself and making that first contact is the real thrill of Ham Radio. I know guys that have built their way up to a 100 watts over years of hamming. But it was always the thrill of doing it oneself that made it wotrh while. I have been a guitar player for over 40 years, The absolutely best amplifier is the 40 watt tube type that I built myself--35 years ago and still using it.!!!!

4243. Re: [SkyWires] Re: Megaloop

Yahoo group: SkyWires
Date: 2013-05-02 09:20:19 UTC
From: raymond mitchell
Topic: 4213 Message: 4243

On 80m NVIS from Oregon to East Texas 100W or less cotact may be 5% to 15% of the time. When the noise floor is S9 (mine is S7 to S9 and I do not get to choose what it will be at any given time) with 1000W+ my brother can tell me if dad has fuel for the generator, both in East Texas, and when they expect power and phone service to resume. Some times it is over 6 weeks (after Ike) before their phone & power returns. If they need emergency services I can make the call into a nearby city (Houston) where phone service is not off as long.

My QRP rig in 1968 was 75W to 125W. I used the Horizontal tube, transformer, HV deck (rearanged), a hand wrapped loading coil, and the UHF tuner with some fins missing to make a sweep tube final for my QRP rig. There is an art to pulling weak signals from the static and as a net control I get to practice that art. But if given a choice I will take and give a 5/9 communication every time. And a good antenna is the best place to start. And a cloud burner can turn sporadic contacts into regular dependable communications with friends and family.

There really is not such a thing as a "full size" antenna. The efficiency of an antenna and paying attention to wave propagation and atmospheric conditions is. And I am also not referring to ham radio operators that are gearing themselves for emergency communications.

Cb Radio has proven itself to be reliable local emergency communications. I am referring to the purebred"Ham" that is interested in the hobby aspects of Amateur Radio. Myself and myself were never into "pegging" someone meter. We were interested in making contact using homebrew and very low power transmitters. Dad used a "Goonie Bird" for years on 2 Meters and we had some impressive contacts using a simple beam with 7 watts input. And we were also part of the Local ARRL Air Force Civil Defense network here in lower NY State. If anyone reads the ARRL Ham Radio handbook, it suggests to start out small.

--- In SkyWires@yahoogroups.com, raymond mitchell <ramitchell777@...> wrote:

>

> A full size ant helps ya keep in touch with friends and family. Sometimes 10W to 40W will do fine, many times it will not. Other times when folks say the band is dead ya need 1000W or better for reliable communications. During Ike and Catrina the radio provided the only reliable communications. Many times 100W was fine, most of the time 500W or so was fine, but it was rare when 1000W+ could not get through. The antenna is the most important part of our system. Still a good cloudburner, while hooked to that antenna, has proved useful.

>

>

>

> Anyone can go out and buy $4000 worth of equipment ,and get all over the universe but to build a 3 or 4 watt transmitter yourself and making that first contact is the real thrill of Ham Radio. I know guys that have built their way up to a 100 watts over years of hamming. But it was always the thrill of doing it oneself that made it wotrh while. I have been a guitar player for over 40 years, The absolutely best amplifier is the 40 watt tube type that I built myself--35 years ago and still using it.!!!!

4246. 160M-80M-40M Sky Wire Horizontal Loop Antenna

Yahoo group: SkyWires
Date: 2013-05-11 19:40:54 UTC
From: rocketman10002003
Topic: 4246 Message: 4246

1 Dose the sides of the antenna have tobe at a specific lenght when used with a Palstar AT4K antenna tuner. I plan on using a ladder line to feed the antenna?
2 I have the space to make the sides 170 ft. for a total length of 680 ft. Is this tunable?
3 I plan on hanging the wire 55ft. in the air, is this to high?
4 Is there a way to provide lighting pertection with out unhooking the antenna from the tuner?
5 Any thoughts on this project would be appreciated.
Thanks for your time Dale KC9WXG

4247. Re: 160M-80M-40M Sky Wire Horizontal Loop Antenna

If the entire length of the antenna is achieved without any real sharp right angles, I don;t think the need to be equal.
Any antenna array is tunable,,it depends on the frequencies you will be using it at.
The higher the better!!!!!!
A lightning arrestor at the terminal point to a good earth ground should suffice but personally I would have a knife switch to connect the antenna array directly to ground when there is strong lightning activity to avoid any bleed over.

4248. AW: [SkyWires] 160M-80M-40M Sky Wire Horizontal Loop Antenna

Yahoo group: SkyWires
Date: 2013-05-12 09:23:34 UTC
From: siegfried jackstien
Topic: 4246 Message: 4248

Your palstar should easy tune it BUT ... I would simulate that length with an antenna soft (reason is to know what impedances your tuner has to handle on different bands)

Why not make a resonant loop (168m or 1wl for topband) ???

Tuneable is even a wet noodle ... question is how good will it work ...

Height influences the angle of the antenna (cloudwarmer or not)

At 55ft height it should work well for 40m on dx ... and be a cloudwarmer on 160 and 80

You can add a spark gap at the tuner end of the ladderline ... but disconnecting would be way safer cause even a nearby strike could kill your tuner (and other things)

From: Warren
Topic: 4246 Message: 4249

With proper planning and installation you should not have to disconnect the antenna during lightning storms. I'm sure you have FM and television broadcast stations in your area, not to mention cell phones, paging systems, and so on. They all continue to operate during any type of weather including lightning. There is no reason for yours not to as well.

I plan to install a 160M loop antenna, supported from four trees. It will use ladder line to a 4:1 balun mounted outside. From there, coaxial cable will carry the RF to a tuner and the transceiver. The balun provides a DC ground for everything. The balun will be close to the main electrical entrance for the house. The coaxial cable shield will have a copper strap connected and it will be bonded to the AC entrance ground. Several radials and extra ground rods will be placed there as well. Short of a direct hit, which is difficult to protect against anyhow, I have no concerns with lightning moving through.

There are several lightning protection and grounding documents written by FM broadcast companies. Nautel, Broadcast Electronics, and Polyphaser have very good pre-installation suggestions. I've summarized my thoughts on them, and provided links to the originals in this document.

4250. RE: [SkyWires] 160M-80M-40M Sky Wire Horizontal Loop Antenna

Yahoo group: SkyWires
Date: 2013-05-12 18:47:29 UTC
From: John Hamilton
Topic: 4246 Message: 4250

I had steering diodes in my K2/100 power amp taken out by static generated during a wind storm. I placed a 1 meg carbon resistor across the feedline to bleed off the static and haven't had a problem since. This will work for any long-element antenna.

Subject: [SkyWires] 160M-80M-40M Sky Wire Horizontal Loop Antenna

1 Dose the sides of the antenna have tobe at a specific lenght when used with a Palstar AT4K antenna tuner. I plan on using a ladder line to feed the antenna?
2 I have the space to make the sides 170 ft. for a total length of 680 ft. Is this tunable?
3 I plan on hanging the wire 55ft. in the air, is this to high?
4 Is there a way to provide lighting pertection with out unhooking the antenna from the tuner?
5 Any thoughts on this project would be appreciated.
Thanks for your time Dale KC9WXG

4251. 40m loop

Yahoo group: SkyWires
Date: 2013-05-18 21:24:29 UTC
From: g0mgm@ymail.com
Topic: 4251 Message: 4251

Im new to the group and have just installed a loop but im having a few issues getting it resonant. The setup is roughly a diamond shape with one corner being 34 feet high and the other three being abt 25 feet high.

The feed point is at one of the 25 ft high corners with rg213 coax. Currently its Swr is 2.8:1 at 6.8MHz on the analyser so its still too long at 143.5ft for 7.07MHz which is what i want it centered on. I have already cut abt 1.5ft off and the resonant freq has moved but no improvement on swr.

Any sugestions on how to improve it? I can try a 4:1 balun tomorrow but was wondering if I should change the feedpoint?

Thanks

I resonate my big (180 odd meter circumference) horizontal quad loop
by feeding it with 450 Ohm ladderline and adjusting ladderline length.
There's a web site somewhere that shows how someone uses a series of
relays to switch in and out "loops" of ladderline to achieve resonance
on several bands. I can probably find it if it's of interest? I also
think having a PROPER balanced matching unit is a real boon with
loops, I am building one based on PA0FRI designs, using a vac cap and
a big roller inductor. http://pa0fri.home.xs4all.nl/ATU/Smatch/smatcheng.htm

I don't think changing the feedpoint on a horizontal loop makes that much
difference. I love my loop, very low noise, simple, discreet, and also
CHEAP :)

Good luck Rob!

A one wavelength long loop does not have a 50 ohm impedance. It is around
100 or 120 ohms. 120 ohms means an SWR of 2.4:1 on a 50 ohm feedline.
Trimming the loop shorter or longer does not fix that. If you want to get
the SWR down on the coax, you need to transform the impedance down to 50
ohms resistive. It can't get there without help.

Plus the balanced/unbalanced mismatch between the coax and the loop could
be making it worse.

A 4:1 balun might bring the feedpoint down to 25-30 ohms, still giving you
an SWR of around 2:1.

This might be what you are thinking of:
http://www.w5dxp.com/notuner.htm

He is using it on a dipole, but it should work for other types too. The key is using the length of feedline for matching:

The No-Tuner, All-HF-Band, Horizontal, Center-Fed Antenna is our old friend, the 80 meter halfwave dipole dressed up a bit. By varying the length of the 450 ohm ladder-line feeding the antenna, we can achieve an SWR of less than 2:1 on all frequencies on all HF bands with the exception of the lowest part of 80m. On 75m, we are feeding the antenna with a half-wavelength of ladder-line. On 40m, we are feeding it with 3/4 wavelength of ladder-line.

This should work for a loop also.

Thanks for the replies. Very useful info.

I am a bit confused now as with my MiniVNA I see a 34.72 Impedance and 24.47 Reactance at 6.8 MHz. As you say I would have expected something like 100-150 Ohm Impedance there?

If you are looking for a low SWR you need a 2:1 transformer and yes they are as easy to make as a 1:1 or 4:1. If you install a 4:1 it will be off in the other direction because you antenna is about 100 ohm and your coax is 50 ohm. The other fix is to use a coax transformer, a 1/4wl of 75 ohm coax at the feed point.

If you make a coax transformer don't forget to figure the velocity factor of the cable use.

Are you measuring this directly at the loop itself?

If you have feedline between the VNA and the loop, the feedline will
transform the impedance (by taking you part-way around the Smith chart).

If you want to know the impedance at the antenna, you can use feedline in
your measurement as long as it is a whole number of half-wavelengths long
at 6.8 MHz (and if the feedline is very low loss).

4258. Portable Field Day Loop

Yahoo group: SkyWires
Date: 2013-05-21 00:07:28 UTC
From: Gary D
Topic: 4258 Message: 4258

Hi all, I'm thinking of a multi band portable loop for field day. I will be setting up in a field with a 22 foot 3 section extendable metal pole. 80/40/20/10 meter ideally. Perferably Coax fed, as I can use my 1/4 Balun I use at the Apex of my 17M delta loop. I don't have much experience with loops other than the 17m delta loop I currently use, and it works very well. I understand they work best cut for a given band. Any designs welcome. I will be using a portale MFJ antenna tuner with my Kenwood TS/50. Thanks, Gary W3GRD.

1X loop is a 100 Ohm antenna , a 2X loop and larger are close to 200 Ohm

2X in length loop, or greater can be matched with 50 Ohm coax and a 4:1 Balun if

the overall length of the loop is a multiple of the length at that frequency

Even Multipliers will make it a resonate antenna, A 4X and 8X loop will match

the most bands when used with a 4:1 Balun

With the correct resonate length of the antenna no tuner adjustment is needed

on the 7 bands shown

Chart at
http://s1102.photobucket.com/user/KD0ZZ/media/Loop_zps75e5682a.jpg.html

Note to work 80M this way you need a 160 loop

Many tnx to everyone who replied, have now installed the 75Ohm matching section and the antenna is working a treat. Getting 1.3:1 SWR from 7 - 7.2MHz and 55Ohm Impedance and 5Ohm Reactance.

Thanks again.

4263. AW: [SkyWires] No Tune with Ladder Line (switchable lengths)

Yahoo group: SkyWires
Date: 2013-05-22 09:17:02 UTC
From: siegfried jackstien
Topic: 4251 Message: 4263

I change the ladderline length from my 168m loop to balun to make it multiband :-)

On the 2 lowest frequencies (160 and 80) the impedance is low ... with a quarterwave length I bring it up in the range of 400 to 500 ohms and then with a homebrewed 1:9 balun back down to 50 ohms

On 40 the impedance of the loop is higher (also around 400-500 ohms) and then I use a halfwave length of ladderline (that is a quarterwave on 80) to bring that 400-500 ohms down to the balun (and the also back to 50 ohms)

On bands above that the impedance is also higher (cause such a big loop has many wavelengths on 20m and double that on 10m) ...

There the ladderline is almost matched and so ther is no transforming

.... it is a mixed setup with matched conditions on higher bands and with transforming with the lengths of the line on the lower bands

4269. Re: Portable Field Day Loop

Yahoo group: SkyWires
Date: 2013-06-03 16:10:50 UTC
From: Alan
Topic: 4258 Message: 4269

Hi Gary, just saw your post and though I'd share with you an antenna I built in a hurry for last years fd. I saw it in the arrl field day manual. Its a 40m fullwave loop in a square, it requires one corner as high as possible and thats where you feed it directly with 50 ohm coax. I used it last year and was pleased with the results. Yes, I had to use a tuner on a couple of bands but it really worked well on 40 and 20 without the tuner. I'm sure there is lineloss but keep the feedline short as I did 35 ft of rg8x. I pulled it up in a tree and it had a nice slope to it. It was our main 40-10 meter antenna. I had a couple of other antennas for 15 and 20 but the loop was much stronger. Hey we won 1A in our Section..hope this helps, 73 Alan

>
> Hi all, I'm thinking of a multi band portable loop for field day. I will be setting up in a field with a 22 foot 3 section extendable metal pole. 80/40/20/10 meter ideally. Perferably Coax fed, as I can use my 1/4 Balun I use at the Apex of my 17M delta loop. I don't have much experience with loops other than the 17m delta loop I currently use, and it works very well. I understand they work best cut for a given band. Any designs welcome. I will be using a portale MFJ antenna tuner with my Kenwood TS/50. Thanks, Gary W3GRD.

Thanks, this is what I needed to be inspired to build a new FD antenna.

So a 80 meter Horizontal loop with a 4:1 Balun will be the new FD antenna this year.

And not worried if it's a NVIS antenna on 80 meters....with the Bay area to the north and LA to the south I'll still have plenty to work with this antenna. HAHA Will probably also set up a G5RV.

From: ad6aa
Topic: 4258 Message: 4274

Just a update on the FD Loop antenna. I went ahead and built the 80 meter loop. I used 5 poles and got it up about 20 feet in the air.

It almost always received better than a multi-band dipole we were also using, sometimes by 5 to 6 S units. It appeared to work the best on 40 and 80 meters. On 20 meters it seemed to hear a lot better than it got out. There were a few signals on 20 meters that were S-7, S-8 that could not be worked.

It easily tuned up, with the built-in tuner in the radio, on all the bands.

From: Thomas F Giella W4HM
Topic: 4275 Message: 4275

I've been experimenting with a 300 foot long horizontal loop on 80-6 meters for 9 years. It has been fed with anywhere from 40-150 ft of 300 and 450 ohm window line to Palstar BT-1500A and MFJ-974HB balanced antenna tuners and noticed no problems in tuning or radiation patterns.

Of course on some frequencies a high voltage point has been at the tuner but the tuner handled it with no problems and no RFI in the radio shack.

So from my personal experience the length of the window line doesn't matter, especially if you are going to use it as a multiband antenna. Just use the shortest length you can get away with.

BTW the antenna works really well on 40-6 meters QRP operation and DXing. Also on HF radio shortwave program listening and DXing.

I have a web page on it at http://www.wcflunatall.com/w4hm15.htm .

I have just erected an experimental loop in my small garden. It is too short for full wave resonance at 40m but I plan to put a "tuck" in it to correct this. I am using 15m of 450 ohm window line with a 4:1 balun to feed it

As it is now, I need to use my Palstar AT2K to tune the 40 and 80m bands, but the ATU in my IC-7700 copes 100% with 6m thru 28m.

So do a second experiment

Feed your loop away from the house (ladderline has low loss so no problem!)
... so the "closed side" is close to the house (maybe close to shacks
window?!?)

Now open your loop for the lower bands to have a "bent dipole"

A friend from me uses this "trick" to use his 80 loop on topband as bent
dipole and it works superb ...

On higher bands opening the loop changes the direction of the multiple lobes
so you have 2 different setups to use on the higher bands

From: Hylton Thompson
Topic: 4278 Message: 4282

Thank you for your response Sigi. It has taken me a year to get planning permission from my county council for this loop. This was due to vigorous objections from an immediate neighbour.

The loop is corner fed with the feeder as inconspicuous as possible. It comes down the outside of one of the 4 fibreglass support poles that is located on a corner of my house beside my shack window.

I hear what you are saying but I don't want to provoke the neighbour further by having the feeder in his field of view at the bottom of our garden. The house end of the loop is 2.5 metres higher by the way.

I did open the loop at the bottom of the garden while experimenting and found the resulting doublet was more sensitive than the loop in some directions, as you suggest, but the loop is so much quieter that I prefer to just stick with it, for the moment at least.

I now need to increase its length to get 40m resonance and will probably do this by dropping a fold of wire down. I think this will be better than increasing feeder length because the vertical fold will at least radiate something.

Wow ... trouble with a 40m loop (slightly short) ?!?!

I use a topband loop here and plan to build a REAL big loop (3 wl for topband equals a 6 wl for 80 ... yes I HAVE some room here :-)

>
> The loop is corner fed with the feeder as inconspicuous as possible. It
> comes down the outside of one of the 4 fibreglass support poles that is

Years ago i also was on such a small city lot

I zig-zagged the ladderline in the attic to have a longer run from tuner to loop ...

> I hear what you are saying but I don't want to provoke the neighbour

But for using it on 80 you should open it ...

another band to use ... only for local ragchew ... but another band

and ... yes I know the loop is VERY quiet

> I now need to increase its length to get 40m resonance and will probably
> do this by dropping a fold of wire down. I think this will be better than

> something.

You could maybe lift up the feeding point and have the loop sloped somewhat?!? ... that would also increase the length

What about adding radials below the feeding point and use the loop and the vertical feedingline against ground (vertical with a big tophat)

A few days ago the question was presented about running a large loop thru trees VS cutting down a thick forest for a clear path. I have received no answers as of yet so I am tossing to question of to a few more people. I have a good performing 80M size delta loop now in my yard. I have been thinking about one 3 or 4 times larger but that would mean a lot of cutting or contact with trees. Anyone have experience with antennas thru trees on HF. I don't need the fire wood, I heat with wood pellets and have a bad back so would like to avoid any excess cutting and can't afford a D8.

Hi rich

I would only cut out some branches and not the whole trees if possible

The damping of trees is very low (I have half of my 160m loop trough trees)
... so only the branches that really are in the way ...

You maybe could add some more insulators and secure the loop on the trees
along its run on just some more points

Lower sag ... and lower tension on the ends needed

Dg9bfc

Sigi

Ps how do you plan to erect the loop??? Slingshot? Cross-bow? Ladder?

I may be in luck... A city nearby has auctioned off street light poles. An acquaintance bid $40 for one and got it for that.

I think I will contact city hall to watch their auctions for more. It appears they are replacing the steal poles with the ornate cement poles.

From: O-B-1
Topic: 4287 Message: 4287

I am in transmitting, merely receiving.

I have read of many connections from the antenna to the tuner.

For receive only, I should be able to just use a coax air choke to reduce the RF currents on the shield from sources in the house, no?

If you're just receiving, no need to worry about RF on your shield. Any noise you pick up from the house will be picked up by the antenna....much more than you might pick up on the coax.

From: Andy
Topic: 4287 Message: 4290

Almost everything about transmit antennas, is also true for receive antennas.

This includes common-mode currents, or "RF on the outside of the coax". While you won't get burned by touching it, it is generally undesired because it means the feedline is acting as part of the antenna and will be picking up signals, and unless you want that to happen, you should try to see that it doesn't. By choking off those common-mode currents, you stop them from finding a path into your receiver. In other words, reception might be quieter and cleaner if you make the effort to stop common-mode currents by using an appropriate balun.

If an air choke ("ugly balun") was good enough for transmitting (at the frequencies you are using), then it will be good enough for receiving. If it wasn't adequate for transmitting (ignoring the power handling issue, which the air choke shouldn't have), then it would not be adequate for receiving either.

Common-mode problems aside ... at HF and MF frequencies, a receiving antenna can have quite a bit of loss and still work well. That's because the dominant noise source on those frequencies is either man-made, atmospheric, or cosmic; not internal to the receiver electronics. So reduced signal strength doesn't degrade the signal/noise ratio. This is one area where a receive antenna can differ quite a bit from a transmitting antenna. But you still have the same concerns about common-mode currents because it makes the receiving antenna more susceptible to picking up locally generated man-made noise.

Topic: 4291 Message: 4291

I don't have enough yard space to fit a one wavelength horizontal loop skywire for 80m. Has anyone ever tried using twinlead as the antenna element and twisting the wires at the feedpoint to double the physical length? Or am I describing a horizontal DCTL?

I will be feeding the antenna with TV twinlead and using a Tentec 229 transmatch in the shack.

My original plan was to try using a short loop of regular wire (less than 1 wl.), but then this idea occurred to me. I have a big spool of TV twinlead I am not using for anything else...

How much room do you have??

Maybe you can make a shorter loop and live with that (if it is not that much shorter as needed) ... or you can "zig-zag" one or 2 sides maybe?!? (between this bush and the garage and the tree and ... you got the idea)

Or ... build a 40m loop

Add a switch at the opposite of feeding and work the loop as "bent dipole" on 80 (a friend does this on 160/80 ... flipping the switch also changes the lobes on higher bands)

It will radiate even if it isn't a full wavelength circumference. It just won't present a resistive load. You can change that by adding extra wire in the right places, which doesn't need to be stretched out into a loop. I saw somewhere about adding capacitance or inductance to the loop, which you do by adding wire at current nodes or voltage nodes, to make the loop seem electrically longer.

I have seen very little written about large multi-turn loops.

You could zig zag one of the horizontal loop antenna legs in the horizontal plane. It's called a linear load and it will radiate. I've done that in the past sucessfully on a 160 meter 1 full wave horizontal loop.

If you use twin lead for the antenna element you will end up with lot's of RF signal cancellation.

From: w2vmc
Topic: 2195 Message: 4298

Hi,

I put up one of these, yesterday, and it does seem to have gain over the old 75M full wave loop I had up at the same height. It also seems to be just a tad "quieter."

I didn't realize that this is what I was putting up when I did as I was looking for a way to cram 160 meters worth of wire in 75 meters worth of space. After seeing how well it worked on 75M, I discovered the information you posted. "So," I thought, "this is what I did!"

Thanks for posting it!

4299. 40 Meter Loop Antenna on 80 Meters and WARC Bands

Yahoo group: SkyWires
Date: 2013-08-29 06:50:30 UTC
From: kp4md
Topic: 4299 Message: 4299

Full wave loop antennas present non-reactive loads on their resonant frequency and harmonics thereof, but their high reactance between these frequencies may present matching problems at the transmitter end of the transmission line. These vector network analyzer measurements over 3 to 30 MHz demonstrate the effect of lengthening a 140 ohm zip cord transmission line to a 7 MHz full wave loop antenna from a random 37.9 feet to an electrical half wavelength at 7 MHz (51 feet). This eliminated skewing of the natural resonant frequencies of the loop antenna at its natural fundamental and harmonic frequencies. Also, the impedance transforming characteristics of this transmission line at frequencies where it is also an odd multiple of a quarter wavelength (3.5, 10.5, 17.5, and 24.5 MHz) transformed the loop antenna's high impedance at those frequencies to a low impedance, eliminating high RF voltage on the matching network and facilitating transmitter matching on 3.5 MHz and the WARC bands.

My 40 meter full wave antenna is 140 feet of wire in a nearly square loop http://www.qsl.net/kp4md/kp4mdnec2.htm <http://www.qsl.net/kp4md/kp4mdnec2.htm> . I intend to use it on all HF bands, including the WARC bands. As its impedance varies widely over this range I use 18AWG zip cord speaker wire as a balanced transmission line which is easily wound on a ferrite core to form a common mode choke (1:1 current balun). The final impedance matching to 50 ohms is accomplished by an LDG autotuner attached to the transmitter. I am presently testing this antenna system on all HF bands using frequency hopping WSPR mode. My current WSPR spot reports are posted at http://wsprnet.org/olddb.php?findcall=kp4md&findreporter=kp4md <http://wsprnet.org/olddb.php?findcall=kp4md&findreporter=kp4md> ï»¿

Topic: 4299 Message: 4302

Zip cord , both speaker and AC extention wire, works well as a balanced
feed line on160 to 30 meters.
At 20 and up the loss due to the insulation is 4 db per 100 foot.
This has been tested by ARRL lab and others and reports were in QST.
It has about 105 ohm line impedance and velocity factor of .70.
I use it for feeding a 2 turn vertical loop of 80 foot of zip cord for
mainly
receiving on 80 , 40, and 30 to reduce noise.
However my SGC 230 tuner will tune it from 80 to 10 meters for transmitting
and it works almost as well as my horiz coax fed dipole at 35 feet above
ground.

30 feet of ladder line would increase the effective line length by 60 feet.
As a loading section it would not radiate any significant energy so why not just leave it out?
Build a 240 foot loop, connect to the tuner, and use it.

From: <narikawa@...>
Topic: 4307 Message: 4307

Hi Folks

I am installing a 160 meter horizontal loop antenna before winter snow hits. It will be fun to see how it works over the winter.

I am shooting for at least 550 feet and have a 4 corner supports install in trees. I took time to install pulleys, and the ends terminate at the base of the trees for easy adjustment and maintenance.

I plan to mount an SGC-239 at the feedpoint.

I currently have the SCG-239 connected to an end feed long wire antenna (500 > feet) that has worked very well for years.

What would be the difference if I ran ladder line (15 feet) to the SCG-239 instead of mounting it at the feedpoint (handing in the air)?

No difference in antenna performance ... some bands may be easier to tune (or also some maybe impossible to tune!!!) ... if that is the case then change ladderline length

I feed my topband loop with about 15-16m (don☐t know exactly) windowline ...
and for low band and some other bands I add another 20m with banana plugs
... and at the shack end a homebrewed 1:9 balun

With some cutntry I now have a multiband antenna that I can use on most bands without tuner ... but it took me SEVERAL days to get to that solution

I made an excel sheet for my notes ... and then made antenna and ladderline in different lengths and try again ... till it fits my needs :-)

If you install an autotuner at the antenna (or close to it with some ladderline in between) ... you have to try out all bands and if the tuner does not find a match .. or just a matching point with very high or very low impedance then change the ladderline length and try again ALL BANDS

I modelled my loop and it is not equal on the 3 sides (more or less 40/60/70m) ... feeding in a corner between 40 and 60m run

If you have a direction on the higher bands that you wanna work then you should try to locate the feeding point at the opposite corner of that direction (or in the corner pointing TO that direction ... both setups do work fine) ... I made mine that the max gain on 40 runs north east south west (vk/zl short and long path)

If you have your loop installed ... you will never ever want any other antenna (except a big beam/4sq or similar)

Or in other words ... YOU WILL LOVE IT :-)

Hi Sigi

Thanks for sharing your experience. I got the four corners up yesterday, but today I have a combination of rain and sleet (ice) making my final wire run a challenge.

I was going to mount the SCG-239 inline. This meant that I would need to create a waterproof enclosure and run power. The weight of the tuner would also make the wire sag significantly.

I will get some ladder line ASAP and keep the tuner in a weather proof electrical enclosure (close to radio) and keep the ladder line as short as possible. I think it will be less then 20 feet vertical. This will be a much better installation for me as I can now monitor the tuner.

My goal is to have a multi-band antenna system that will work with normal amateur radio use and ALE (Automatic Link Establishment). My property won't work well for towers, but will support a long wire system.

Once it get everything working I will take some photo and post them so you can see the final result.

Thanks

The autotuner is an unbalanced tuner ... so I would then add a choke on the input AND on the power lines to lift the tuner up rf wise

My friend did the same with his dipole and it works 160-10 ...

Congratulations on getting your 550' loop up. I bet you got plenty of exercise walking around adjusting it. My 550' loop is up about 50-60 feet on average and I am feeding it with about 65 feet of homebrew ladder line with 600ohm characteristic spacing to a homebrew true balanced antenna tuner, with synchronized roller inductors. This allows QRO power when needed too. The feed point is near one of the tree ties so the weight of the ladder line does not cause antenna sag. The antenna and feedline are all 12gauge wire and it works on all HF bands.

Additionally my loop is tied out at 6 trees making it more rounded, maximizing the planer area within the loop and a bit more unidirectional - though not perfect.

It sounds like you live in an area where you get “sticky” snow and ice, as I do. The commercial window line is compromised in the inclement weather, if that is of concern to you. I evolved into homebrew ladderline for that reason and during inclement weather I connect a big old Variac AC supply directly to the loop leads, crank it up to about 20volts at 20 amps through the loop for 20 minutes and melt the snow off the sagging antenna and ladderline. Homebrew ladderline is easy to make too. In any iteration though a 550' loop works great. Good luck with it....

Great idea re the heating, my big loop also suffers ice build up, this
will also give the birdies something to warm their toes on ;)

I plan on starting my 160m loop project shortly but I don't have the trees. I plan to install about 15 ft above ground with the NVIS concept. I plan on feeding with a 4:1 balun and coax. I cannot use ladder line here, too far away from the house. Any thought to the wire length for that height? Some have told me to start at 560 and trim my back if needed.

Thoughts?

Will, K4AAV

Hi Chris

Heating the cable has to be the greatest antenna idea I have ever heard. This could be great in the winter. Ice storms can create a lot of weight. I plan to try different wire to see how they perform.

I will get busy finding Variac AC supply or similar.

THANKS

My main height consideration is the garbage truck. I think it a 80,000 lb unit and I need the wire to provide clearance. The truck has to use my turnaround or they can't pickup by neighbors trash.

I would like to keep it low enough to have NVIS properties.

My roll of wire is about 656 feet.

5m is VERY low ... you heat up the ground ... that□s all

Nvis does also work with higher installatiojn heights..

10-15m would be my goal ... even that is low (compared to wavelength on topband)

At that height it would work "nvis" on 80 and 160 (and also a bit on 40m)

From 40m upwards that loop will be a good dx antenna (an elmer once said to me if you can not make it high ... then make it long)

.... you wrote that the distance is to high for ladderline??? Absolutely wrong! .. as more distance you have as more is a reason to change from coax to ladderline ....LOWER LOSS and multiband use!!!!

5m is very low (compared to wavelength on topband) ... go higher and you have better signals (not heating the worms in the ground)

Hi Sigi

Picked up enough 450 ohm ladder line today to connect the loop to the SG-239 tuner. I need to make some minor corner adjustments, then I can sting the antenna wire.

I agree, higher would be better and still NVIS. Probably anything under 30m off the ground would be NVIS on 160.

However, I do remember an old article in QST where they talked about portable NVIS antennas that were only a foot or so off of the ground. IDK, I guess that's better than a 8ft whip on 160....maybe...

10/25/13 Update

I have corners up and 500 feet of wire pulled. I contacted SCG Technical Support to verify the connection between the SG-239 and the loop antenna. They said 450 ohm ladder line from the loop to the tuner was best and to not cut the loop to NOT cut to the specific band.

I will verify the insulators, connect the ladder line, and test.

Thanks for the feedback, I will keep you updated.

10/26/13 Update (It works great)

I spent most of the day (a lot of walking back and forth) making final adjustments. So far Ia am very happy with the results. The SCG-239 tunes every band and I can't believe the reception and low noise floor.

Thanks for everyone help!!!!

Wow - glad it is working for you. If I am creative I should be able to get ~570' (160M loop) in the air. Won't have an auto-tuner tho. Wondering what the height of your wire is and how it varies??

We have a long wire that is marginal but functional. I want to turn it into a loop.

4324. stringing a large loop across a deep gully?

Yahoo group: SkyWires

From: Ken
Topic: 4324 Message: 4324

I don't have much in the way of tall supports, but I do have a fairly deep gully starting 150' from the house. I'm toying with the idea of stretching a 1000-1200 ft loop across the gully to get some height above ground. It might only be 10-20' above ground on the corners and two sides, but probably 50-80' over the gully.

Any thoughts on the effectiveness of something like this, especially for 80/160?

Thanks,
Ken WA8JXM

Ken the effective loop height will only be 10-20 feet above the ground not the 50-80 feet above the bottom of the gully but it should still work pretty good.

I currently am using a square in shape 288 foot long horizontal loop with each leg 72 feet long. At the four corners the height above ground is 35 feet. The antenna works very well for DXing and contesting on 40-6 meters.

Initially I had the loop up at only 20 feet at the corners as a test and it still worked very well for DXing and contesting on 40-10 meters. Actually I could see no obvious difference between loop performance at 20 or 35 feet.

Tom,

Thanks for the reply. I was out scouting the ravine yesterday and I am kind of giving up on the idea. It's very steep terrain and would be difficult to clear a path. The one leg would be around 500' BUT.... the antenna would actually be below the surrounding ground level on three sides and below the next ridge in the other direction even though the 500' span would be over 100' above ground in the ravine. Yes, it would probably work okay but I don't know that it would be any better than a smaller loop erected in the clear on the ridgetop by the house. I'm not really a DXer, especially on 160 and 80 although I must say I am impressed with how JT-65 pulls out the signals. Right now I'm just using an 80m dipole with an average height of about 10'.

In one way, I have a dream location: 130 acres of land, plenty of room for antennas. Unfortunately, all the big trees are "down over the hillside" with nothing near the house.

4330. RE: 40 Meter Loop Antenna on 80 Meters and WARC Bands

Yahoo group: SkyWires
Date: 2013-10-30 06:49:23 UTC
From: <kp4md@...>
Topic: 4299 Message: 4330

The principle of the 7 MHz full-wave loop operation on 3.5 MHz may be conceptualized by comparison with the HO loop, or halo antenna—a half-wave open loop antenna popular on VHF frequencies. The halo antenna is essentially a horizontal half-wave dipole with its elements curved to form an open-ended circular loop to provide a nearly omnidirectional radiation pattern. The halo antenna is typically fed at its low impedance center point, while its open ends exhibit high impedance. By analogy, the 7 MHz full-wave loop operates on 3.5 MHz as a half-wave halo antenna fed across its high impedance open ends. In this case, the impedance transforming characteristic of a 1/4 wavelength transmission line assists in coupling the high impedance antenna to the low 50 ohm impedance of the transmitter. This situation repeats at frequencies where the loop antenna is an odd multiple of a half-wavelength, that is, at 10.5, 17.5 and 24.5 MHz, near the "WARC" frequency bands.

The 100 ohm zip cord is preferable to 300 ohm twin-lead and 450 ohm ladder line for this application. The loop impedance varies between 80 and 350 ohms at its resonance points and between 800 and 1800 ohms at the midpoint peaks between resonance. For a quarter wavelength transmission line, the impedance seen by the transmitter (Z) is given by Z = Z02 / Zant, where Z0 is the characteristic impedance of the transmission line and Zant is the antenna impedance. Figures 55 and 56 compare these impedance transforming characteristics for 100 ohm and 450 ohm feed lines. The 100 ohm feed line transforms the impedance to 6 to 125 ohms at the transmitter, within the range of most antenna tuning units. However, a 450 ohm feed line renders an impedance range of 110 to 2500 ohms at the transmitter, values that exceed the operating range and safe voltage ratings of most antenna tuners.

I can't believe how well this antenna works. I did not need a choke.

The technical support at SGC recommended "We generally recommend using 300-600 ohm ladder line style lead when connecting to loops or dipoles. This should work very well with your 160m loop. It will also help as it is actually best to not have the antenna cut to a specific band."

I like the combination of the TS-590 and SG-239. I will post some photos.

A choke will isolate the coax from tuner to the rig from the antenna

That will lower the noise that probably the coax could pick up (acts like
you would add a lossy longwire to your loop from common mode current)

Same for the power leads to the tuner (ground aka minus 12v is connected to
ground of tuner ... is connected to output of tuner and so is connected to
your loop) ... isolating BOTH (power and coax) should further improve
performance (lower noise and better s/n)

Hi Sigi

Can you help identify material and a diagram or photos of the choke. I would like to get the parts and install before the snow falls.

Here is a link to a PDF I created with photos of my installation. I is in the file section of the forum.

http://f1.grp.yahoofs.com/v1/9H52UpY6z5bpOq9UdxSJU3HUh7MDxVeScRfoZFaNSou7ygB_Vqmh2mW-ydwRLqrlxi-svpG-pskDkqR75iSAJslwtUKWbq_S2Nt2/160%20Meter%20Horizontal%20Loop%20Antenna.pdf

4334. Vertical loop and MFJ994BRT

Yahoo group: SkyWires
Date: 2013-11-04 15:01:59 UTC
From: g0mgm@ymail.com
Topic: 4334 Message: 4334

Hello

I have just put up a vertical loop, it is approx 180ft long and I am plnning on connecting it to an MFJ 994BRT to tune it. The highest point I can get is only about 25-30fet above ground and the base of the loop is about 6ft abve ground. Its the shape of a rectangle.

I've just been reading some of the documents in the Files area and they recommend using ladder line. Can I not just connect the ends to the tuner?

I have never used ladder line before and my shack is approx 80ft away from the antenna, but if I were to use ladder line all the way back to the shack most of it would berunning about a foot above the ground attached to the garden fence. Would that make a difference to the way it works?

Thanks

Rob

Yes you can if you have a remote tuner.

> I have never used ladder line before and my shack is approx 80ft away from the antenna, but if I were to use ladder line all the way back to the shack most of it would berunning about a foot above the ground attached to the garden fence. Would that make a difference to the way it works?
>
>

Yes, that would be less than ideal for ladder line. It should ideally be several widths away from any metal or ground. My open wire line is 4" wide. If you are using something more narrow, 6" to a foot distance should be okay. It's best to twist the line over distance so as to balance each side to the metal or ground.

The easiest would be an "ugly balun" ...

Next option would be "some turns of coax around a toroid"

Best would be maybe a real 1:1 balun (but that is a bit overkill)

For the power lines same thing ... a choke (or coil in other words) would isolate the tuner rf wise ... but it is still connected to ground dc wise

Thanks Ken. Yes I am planning to use the MFJ 994BRT at one corner of the loop. The tuner will be abt 2 ft above the ground and the corner of the loop will be abt 4ft at that end. I will bring a couple of tails from the corner to the tuner. Fingers crossed it works ok. Rob G0MGM

OK I have connected the loop to the MFJ994BRT and it tunes OK on 30m and down to 10m, but on 40m 60m and 80m it tries and just seems to hunt constantly.

At 180 odd feet it should be more than long enough for a 40m loop but it wont tune.

Any ideas? Is this a resonant length? Or should I feed it through a 4:1 balun with coax?

180 ft is resonant around 5.6 MHz. Too long for 40 Meters (7 MHz) to work properly. The formula to calulate is 1005/F(MHz) = Length in feet. A loop will work on its fundemental design frequency and all harmonivs (even and odd) above it. So your loop should be about 1005/7 = 143.6 feet. Please note that it wil not tune up on 160, 80, or 60 Meters as it is too short, and could cause damage to your antenna tuner. The 143.6 feet is for bare copper wire, and will be about 3% shorter (multiply answer by .97) if using insulated wire. You may have better luck with this length. There should be no need for a balun when using the MFJ-994BRT remote antenna tuner for this application. 73, Mike, KC9Q

Try to add some feet of ladderline could bring you closer to the "sweet spot"

It is too long for 40 and too short for 80

But it should be possible to tune it on that bands

If you are very close to a high impedance point then maybe the tuner will not find a match

Adding a few feet of feeding line shifts you away from that high impedance and high voltage point ... and then the tuner maybe does find a match (and then the antenna WILL work even if it is a bit short)

Dg9bfc

Sigi

Ps why not a bigger loop (240-260 feet) ??? you can "zig zack" it if needed

Hi Sigi

Thanks for the reply. Well I was reading about a random wire loop being tuned with a remote tuner on the SGC website so that I what I was trying to do but the tuner doesn't like it.

What I was going to try first is to put a 4:1 Balun and a 3m coax run to the tuner and see if that worked, if not I will try the ladder line. Currently the loop has a lot of slack in it so it not taught across the tree. I think I have put in a few zig-zags already so cant fit in an extra 60ft unfortunately.

I already have a 40m horizontal loop up fed with a 75ohm matching stub, and I wanted something for 80m and 60m. I guess I wont have enough space for a loop that size, so I may end up putting ladder line on the 40m loop to make it multi band and turn the vertical loop on the remote tuner to a long wire.

I think you'll find that going to a balanced feedline will make all the difference in the world when it comes to tuning. Coax just doesn't allow it. I went through the routine of trying to make coax work, myself, on an earlier antenna. The day I bit the bullet and just pulled down the feedpoint to attach a 300 ohm twinlead was the day I finally started being able to tune & transmit on non-resonant frequencies. Coax just won't let you do it.

Everything that goes up for HF has balanced feedline on it now, around here.

On getting a long enough loop, some people have hung 'spiral loops' to get a loop up in less space, though I have no experience with them. Here's an exchange on that:

That totally depends on the transmitter and/or tuner. There is no inherent reason that coax can't be tuned just as well as a balanced feed can be tuned.

Certain antennas and feedline lengths are harder to tune on various frequencies, but if you have a good enough tuner, coax feed can be used, albeit often with higher feedline losses, of course.

Just for example, I just ran through my coax fed 40m inverted vee and loaded it on all bands 10-12-15-17-20-30-40-60-80m. That was with the internal tuner on the Elecraft K3. The K3 did fail to get a decent match on 160, but I'm sure I could do that with the Palstar tuner.

Not to say that I would actually want to operate with the losses on some of those bands, however! ;-) But I have worked VK land with the 40m antenna on 30m.

Of course, if you have a feed impedance above what the tuner can handle, a 4:1 balun can bring that down into the range that the tuner can hanlde.

Thanks you all for your input, I tried a short piece of coax and a 4:1 balun and it now tunes OK on certain parts of 160m and all of 80 and 60m. I will try some 450Ohm ladder I have and see what that does also.

But I will certainly read the port about putting loops in since I dont have the space.

Has anyone tried the Zip cord loop? I read somewhere about using two core power cord and connecting two of the ends together to make it into two loops essentially?

4349. 160 Meter Loop Antenna SWR w/4:1 Balan

Yahoo group: SkyWires
Date: 2013-11-19 02:17:50 UTC
From: <narikawa@...>
Topic: 4349 Message: 4349

Hi Folks

I have been reading the that use of a 4:1 balun can be used on a 500 foot plus horizontal loop antenna. Tonight I connect a 4:1 balun and used an MFJ-269 to read the SWR. Here are my initial results. Does anyone have data on a similar loop antenna?

How would you interpret the data?

Thanks

I did not have a clear spot for a 160 but have a 80M size, then trimmed it for a good SWR in the 20M phone band. Here is a chart of my readings with a 4:1 balun

http://s1102.photobucket.com/user/KD0ZZ/media/80MLoop_zpsa6e4cfe7.jpeg.html

also your balun may not cover 160 to 6, here is a note about my balun when I made it, mine is centered on 10MHz.

http://s1102.photobucket.com/user/KD0ZZ/media/Balunjpeg_zps41dd0ff6.jpg.html

From: <narikawa@...>
Topic: 4349 Message: 4351

Hi Richard

Thanks for the feedback. I looks like my antenna favors 3.8, 10.15, and 21.45.

I will need to use my SGC-239 to maintain a wideband operation. I may try extending the loop to 800 - 1000 feet next winter and an experiment.

Would a choke help my SWR numbers?

Thanks

If you are looking for a coax fed loop with low SWR points the large length numbers are 566 ft or 849 , 1172 and multiples . Most people over look the high SWR and use ladder line for a random length but you can find a length to give you what you want. Take a look at this chart and you will set there are lengths when all the bands come in. My set up is a delta loop, I tried a larger trapezoid shape but the numbers were no good.

http://s1102.photobucket.com/user/KD0ZZ/media/Loop_zps75e5682a.jpg.html

I hope the notes on the chart are clear, when you look at length you will see the length that will give you a good starting point. I know it worked on 80M size and the numbers are just projected up, I have not tried it myself but M0MCX has had great luck with his 160 delta, coax feed antenna.

http://www.youtube.com/watch?v=SOvhetU1_ps

I have the room for a very large loop but too many trees in the way and if I go too far in one direction I have a 350Kv line across the back of my property and might pick up noise.

A choke will keep RF from coming back down the line but I don’t think it will help much on you SWR problem, but a “ugly” choke won’t hurt anything. I run a 4:1 duel rod Guanella balun so it is a side by side 1:1 choke and the cross wire on one side to make it a 4:1. They are many plans on the web for this type.

4353. 160 Meter Horizontal Loop - Fine Tuning Help Needed

Yahoo group: SkyWires
Date: 2014-01-05 23:31:21 UTC
From: <narikawa@...>
Topic: 4353 Message: 4353

Hi Folks

I am making very good progress with my 525 foot Horizontal Loop. Today I made a contact between MN and FL on ALE.

I am running a Kenwood 590 driving an SCG 239 tuner. The SWR indicated on my Kenwood meter show good SWR except on 18.106 and 10.1455.

How can I get the system to tune better on 18 and 10.

Thanks

You could consider playing with ladder line feeder lengths, or the
ultimate, with no matching unit needed at all:

Try longer and, if it will reach, shorter lengths, also you could mess
with the actual loop circumference. My 180 odd meter loop is not good
on 10 meters, ATU is peaky, easy to get RF in the shack (and my
PC's....). I intend doing the relays and various loops of ladder line,
as per the link. One day.... :)

From: <narikawa@...>
Topic: 4353 Message: 4357

I will try experimenting with the length of the feedline first.

Right now it is -13 degrees and tonight it will get to -30 degrees and the ladder line is very stiff. I have heard about various external chokes that could be placed on the ladder line.

I run ALE and the antenna must be broadband between 1.8 -- 28.32. The antenna would be perfect if I could get 18 and 10 to behave. ALE is constantly moved between bands.

Another possibility is a different balun. The built in balun on my MFJ 962-D tuner, even with the built in roller inductor was not the best so I made my own then added a switch on balun so it could be a 4:1 or a 1:1 , for the best SWR.

http://s1102.photobucket.com/user/KD0ZZ/media/4to11to12.jpg.html.

The basic Guanella current balun layout I used is on

http://s1102.photobucket.com/user/KD0ZZ/media/Balunjpeg_zps41dd0ff6.jpg.html

I have Googled this Ale stuff, and it seems it's resilient comms
software that constantly channel hops (ale ---- hops....?).Not sure
how you would drive the antenna feeder switching, sounds tricky.I
hadn't heard of this ale stuff before save down the pub.

Thanks for the tips on cutting Acrylic Rich!

Hi Rich

Thanks for your idea. I just ordered some knife switches. I how to get them soon.

I went outside (-16 degrees) and reset my SCG 239. Here is what I get now.

100 watts w/CW Tuning (I get rf noise on my PC speakers on 21.0960)

Freq SWR (read on Kenwood 590 display)

3.5960 1.25 7.1020 1.25 10.1455 1.75 14.1090 1.50 18.1060 2.00 21.0960 1.00 24.9260 1.00 28.1460 1.50

Change the ladderline length from loop to tuner

Adding a few feet may help here :-)

I have a topbandloop fed with ladderline and a homebrewed balun (sits inside my manual tuner)

On most bands I do not need the tuner (and on the other the swr is very low so tuner losses will be low)

I made an excel sheet for my notes (sent to you with direct mail)

Open it and see my results :-)

I use 2 different lengths of ladderline (short run from loop to shack and the added length is "plugged in" with banana plugs)

With 3 days of try and error (yes it took a while!) I now have a REAL multibandantenna

Hi Folks

I really appreciate all the feedback.

- I have reviewed http://www.w5dxp.com/notuner.htm http://www.w5dxp.com/notuner.htm and this is very good information. I ordered several knife switches to experiment with.

- I will get some more ladder line so a can experiment with the feedline lenght once it get warm enough outside.

To work on ALE (Automatic Link Establishment) I need a mutliband antenna and scan about 1 band per second and periodically transmit on each band (3,7,10,14,18,12,24, and 28). This means that antenna system must provide rapid switching. The SCG 239 seems to work very well. Yesterday I got ALE working across all bands after performing a "hard reset" on the SCG 239. After the reset I got the following SWR reading on the Kenwood 590 display.

Freq SWR (read on Kenwood 590 display)

3.5960 1.25 7.1020 1.25 10.1455 1.75 14.1090 1.50 18.1060 2.00 21.0960 1.00 24.9260 1.00 28.1460 1.50
I will continue to tweak the antenna so it a good match on as many bands as I can achieve. The SCG 239 seem to adapt to the band that have high SWR (10, 14, and 28).

What are some other tweaks I can work on further fine tune the antenna system?

Thanks

http://www.w5dxp.com/notuner.htm

You should bypass the sgc and tune the loop and ladderline till you got the best overall compromise ... then the tuner has only low mismatch (and so low losses inside) ...

After that you should be "ready for take-off"

If you can not find a good compromise (low swr on all bands) then you shoulkd try to lower the swr especially on the bands that now have a higher swr (17 and 30m) ... then after putting the sgc back "online" you should have a low swr on ALL bands

From: <narikawa@...>
Topic: 4353 Message: 4366

Update 1/11/2014

I think I am close. I have ALE up and running. I have made soundings to Australia and Sweden several times a day for the last week. Very strong signal between MN an FL.

The 525' 160 meter horizontal loop seems to be doing well on 100 watts.

Thanks for your assistance!!!

4367. Horizontal Loop Antenna - Grounding

Yahoo group: SkyWires
Date: 2014-01-29 03:25:14 UTC
From: <narikawa@...>
Topic: 4367 Message: 4367

Hi Folks

I have a 525 foot Horizontal Loop Antenna that is performing very well and I am tweaking it. I install point-to-point ground from the ground rood to the radio case and it reduced RF.

I understand that the large Horizontal Loop Antenna builds up a static charge. What are you folks doing for grounding?

Thanks.

From: Mark Graybill
Topic: 4367 Message: 4368

Mine goes through a coax feedthrough after a balun which has the shield side run to my ground. Inside I use an Alpha Delta switch to ground it when not in use (which is tied back into the same ground.)

If I were bringing the balanced line into the house, it would go to a knife switch that would be in the grounded position when not in use.

Aside from the necessity of grounding the loop when not in use, what about the use of a coil to ground to bleed off the static charge during normal operation? I have used this on a longwire before. The coil (L) would have a Hi Z at RF, but readily takes the static (DC) to ground.

Topic: 4367 Message: 4370

Hi Mark & Bill

Thanks for the feedback. I have the loop connected to an SCG-239 tuner. A short 15 foot length of ladder line is connected to the input (signal and ground) and the input is 12 volt DC and coax from my Kenwood 590s.

My Options:

(1) Run ground braid from the grounding rod to the shield of the coax connector.
(2) Coil to ground

I just got some knife switches, but I am running ALE and the radio runs 24/7. I should check my insurance policy?

I saw this device and ordered one to test.

http://www.arraysolutions.com/Products/AS-309H.htm

Have you seen this device before? What do you think about the concept?

Thanks

Not having run either a loop (yet - it is on the short list!!!), or feeding with balanced line, I have not tried that. Looks good. How it may compare I cannot say. There are individual line arrestors - guess they could be connected up as a pair. But that product looks good. I'd compare specs...

I would still run a coil or resistor to ground. Not for direct hits, but to bleed off the charge that builds up. It is simple to do: http://www.k0bg.com/static.html

See this informative article:
http://www.reeve.com/Documents/Articles%20Papers/AntennaSystemGroundingRequirements_Reeve.pdf

Also: http://taarc.rebelwolf.com/images/Grounding.pdf

http://elecraft.365791.n2.nabble.com/static-buildup-on-antennas-td7562400.html

Found this article:
http://oh7ug.net/index.php?option=com_content&view=article&id=344:stat.
Good information for static buildup on antenna wires. Just a bleeder to ground. The bleeder was constructed with the three 10 Mohm 1W /3.5 kV high voltage resistors in parallel.

ALE sounds interesting - tell me more!

The AS-309 looks better than a homebrew ground rod with spark plugs on it as spark gaps. I'd definitely consider using one.

Topic: 4367 Message: 4373

The SGC239 has the RF output at DC ground via T1 at the output. That will provide continuous static discharge for whatever antenna is connected.

I would be concerned with multiple ground points not properly bonded together. If you experience a ground surge through another source such as the AC feed from the house it will look for a path to dissipate. It may see the ATU ground and find a path via the feedline and the transceiver. Unless you have the system bonded properly your transceiver will act as a jumper between the two grounds. It could experience considerable current and potential damage.

A 500+ foot loop is in the works for here as well. It will have balanced feed to a Balun Designs 4115 4:1 current balun. The coax will enter the house very close to the AC entrance where there will be a copper bus bonded to the electrical panel. A double Type-N connector will accept the line to the balun and another to the transceiver in another room. The line to the transceiver will have a few turns through a toroid. Two copper straps run from the electrical panel to the operating desk to keep everything at the same potential. The AC entrance will have an added ground rod as well. I have my satellite TV lines connected the same way. They enter near the AC entrance, bond to the same ground bus, couple loops through the toroid and then to the TV. If there is a direct hit or a large AC entrance surge the entire house, including radio equipment will remain at the same potential. There will be little or no current passing through equipment.

Add a choke to the 12v dc line ...

And add a choke (balun) to the input side of the tuner

...

Now your tuner is isolated rf wise (floating) and that keeps your ladderline
well balanced

Now ... add your ground connection at the trx side of the balun

Your loop now has a direct dc connection to ground

Hi Warren

Thanks for the feedback! To ensure I understand properly, the SCG-239 will discharge static by design?

I have a single point ground and have a separate flat wire braid going from the ground rod to each piece of equipment.

I just received an Array Solutions AS-309H "Ladder Line Twin Line Arrestor", what do you think of this device?

http://www.arraysolutions.com/Products/AS-309H.htm

I plan to install the AS-309H once we get out of -10 degrees weather. The ladder line is very stiff at these temperatures.

I also have some Alpha Delat TT3G50 arrestors that I plan to put between my Lenwood 590s and the SGC-293 (very near the actual ground rod.

I am very happy with the big loop, I can't believe how well it works in term of a multi-band antenna.

I am using ALE and the system will be on-line 24/7. I plan to verify my insurance coverage and maybe look into ARRL insurance.

I believe in learning by asking, reading and doing...

X(l) = 2 * Pi * Frequency (Hz) * Inductance (Farads), so at 7 MHz 500 uH (.5 mH) gives you about 22K of reactance. Probably high enough not to bother your antenna (50 to 400 ohms), but will bleed off static.

Play around with the values - here is a good calculator online:
http://www.calculatoredge.com/electronics/reactance.htm.

Here is a coil calculator: http://www.66pacific.com/calculators/coil_calc.aspx

You can also plug formulas into Excel (or Open Office - it is free!). Do that and check your calculations against an online calculator. Then you can learn to make a toolbox for yourself. You can add graphing, etc.

After reading the links I sent you I will probably make sure I have mine grounded with either a coil or resistors as suggested. I had a coil on there awhile back - need to check it! Also simply putting 3 each 1Meg resistors on a coax connector and putting it on a TEE to your antenna connector will keep those static charges down. The amount of static that can build up from wind, rain, snow or dist is frightening! And damaging to your Rx front end!!

A bleeder (coil or resistor) can be tied from your loop to ground outside, or simply put the resistors across your coax terminals. That is NOT lightning protection - that is another whole chapter! See the links on that - there is a lot of good information, and the balanced line protector you posted would be a great place to start.

Question for you - how do you make use of ALE? I think it would be very interesting.

Topic: 4381 Message: 4381

Hi guys, I have tried this one a few other antenna groups but with no help so far, trying to find the winding details for a 2.5:1 air core balun for a loop antenna (not toroid I have those details) I know a guy in the US sells them and has good reviews so want to try one out of interest but shipping one out here to the UK is just not cost effective for the cost of a plastic tube former and some old wire, I have heard many arguments against these things but have had good results with a 4:1 air core balun on another antenna I use so would like to try one against the toroid balun on a loop out of interest. Any winding details or a link for them please as Ive searched and searched and come up blank.

4382. WINTER FEEEZE - Heating a 160 meter horizontal loop antenna

Yahoo group: SkyWires
Date: 2014-02-22 21:13:16 UTC
From: <narikawa@...>
Topic: 4382 Message: 4382

Hi Folks
I Minnesota we just had the worse snow.ice conditions in many years. There was about 1" - 2" of snow/ice on every part of my big 160 meter loop. The corner spring did their job very well and many parts of the loop sagged over 10".

Put on the snow shoes (the largest commercial available) and still was over my knees in snow. I made my way to corner supports and pulled the support out 15' then let them snap back several times (hard work getting through the snow, and sweating like a pig). This removes about 50 % of the covering. The rest I have to use a very long paint pole to break the snow/ice from the rest of the wire.

Someone suggested disconnecting the antenna then using a variac transformer to heat the wire. I have planned to do this next year, but I am now a little more motivated to get it done before next winter.

Can someone who has none this provide me part numbers, sources, and operating procedures?

>old message about this technique found:

Congratulations on getting your 550' loop up. I
bet you got plenty of exercise walking around
adjusting it. My 550' loop is up about 50-60
feet on average and I am feeding it with about 65
feet of homebrew ladder line with 600ohm
characteristic spacing to a homebrew true
balanced antenna tuner, with synchronized roller
inductors. This allows QRO power when needed
too. The feed point is near one of the tree ties
so the weight of the ladder line does not cause
antenna sag. The antenna and feedline are all
12gauge wire and it works on all HF bands.
Additionally my loop is tied out at 6 trees
making it more rounded, maximizing the planer

area within the loop and a bit more unidirectional - though not perfect.

It sounds like you live in an area where you get
□sticky□ snow and ice, as I do. The commercial
window line is compromised in the inclement
weather, if that is of concern to you. I evolved
into homebrew ladderline for that reason and
during inclement weather I connect a big old
Variac AC supply directly to the loop leads,
crank it up to about 20volts at 20 amps through
the loop for 20 minutes and melt the snow off the
sagging antenna and ladderline. Homebrew
ladderline is easy to make too. In any iteration
though a 550' loop works great. Good luck with it.... 73 Hank N2MU

4384. RE: WINTER FEEEZE - Heating a 160 meter horizontal loop antenna

Yahoo group: SkyWires
Date: 2014-02-24 15:50:33 UTC
From: <hmlong@...>
Topic: 4382 Message: 4384

Hi,
I'm the person that posted the variac idea previously...
I can appreciate your description of sweating like a pig when you go through the snow as I have experienced the same when sinking into 2' to 4' of frozen snow while attending to my antenna or getting logs for extra heating. It's enough to create a panic attack! I'm sure your weather was worse than mine here in North-Central NJ though...

I don't have any suggestions about a specific variac etc. but this year the temperatures here were so cold (0 to 12 degrees F daily) that 20volts at about 20 amps was not enough to clear off my 12gauge 550' loop quickly, and I had to leave my big old variac on for a long time before the ice started to flake off in sections with the help of what little sunshine there was after a storm.

Additionally I had better results when I preemptively applied the variac current as the storm started. My ladder line is separated at about 600 ohms and is made of fine multi stranded 12gauge insulated wire with plastic spreaders at ~4foot intervals... It doesn't get clogged up with ice bad enough to degrade the output as it is insulated and does not ice bridge across the wire like the closer spaced webbed commercial stuff does. The variac does also clear the feedline to some degree anyway, though.

My variac weighs about 35lbs and has no ratings on it. I was concerned that it might burn up given that the current (about 20-25 amps) is displaced only among the few secondary turns that bring it up to 20-25vac rms... I could smell it beginning to cook!

So as a recommendation to you, the important thing is to power the wire with something very "hefty" and depending on your wire gauge you will need to determine the total resistance for the applied voltage and current. I figure that about a watt/foot applied to 12gauge wire will handily fight stubborn weather conditions if something else doesn't burn up first.... I have an old IBM transformer from the old days of giant computers that puts out about 35volts and judging from the wire gauge it appears to be able to handle 50 amps or more. So I may cannibalize that for the future given that we seem to be getting severe weather trends now...
The loop is worth the efforts though... It is an amazingly simple antenna that works well on all HF bands..
73 Hank N2MU ...-.- ..

Great idea, Hank. What you need is a big old step-down transformer, maybe 4:1, so you don't overload the variac. I once had some big transformers from an industrial voltage controller - several servo-driven triacs and step-down transformers, then step-up back to line voltage. Lost most of them in a move. A welder comes to mind. Interesting question about Teflon-coated wire, but I bet the ice would get it as well! Worth a try! If I ever get my loop built (and we have another ice storm in GA) I'll try the variac trick.

Open up at opposite of feeding point and use your 40m loop as a 80m "bent" dipole

No lossy coil and can be used on higher bands without coil working like a trap/lowpass

Topic: 4391 Message: 4394

YES, but you have to make a choice of which compromise you are willing to live with.
If you open the loop at the point opposite the feed point and make it a bent dipole,
it will work well but have a very low impedance on 80. Perhaps 5 to 10 ohms.
This is because it is a bent 1/2 wave dipole.Your tuner will have to tune this low impedance.
However with open feed line, 450 or other, it will still be an all band antenna.

If you add a coil you increase losses and may prevent it from working on some frequencies.
If you add a 1/4 wave 40 meter open stub at the point opposite the feed point,
instead of leaving it open,It will automatically switch from a closed loop on 40 to a folded 200 ft
dipole and still work many bands with a tuner.

You have to decide what frequencies you want it to work on and then thew lowest loss possible.
But, good news is that it will work and any antenna is better than no antenna.

4396. Multi turn skywire

Yahoo group: SkyWires

From: findsimongough@...
Topic: 4396 Message: 4396

Just wandering if anyone has played with multiple turn Skywire loops. I have a very small plot and the largest loop I can accomodate is 94 feet in circumference, this gives me a lower frequency limit of around 10.7 Mhz. In theory if I was to use two turns giving me 188 feet my lower limit would be 5.46 Mhz. Well that's the theory anyway. Has anyone on here tried this and if so how did it perform?

Simon

I had a 270' two conductor loop fed with 67' of 450ohm ladder line that I recently modified. I had it configured for two turns of 270' for a total of 540'. It did not work well on 160m, but pretty good on 80m - 10m. I cut the connection making it a loop so I now have a 540' doublet using the two 270' conductors. it is still in the circular orientation but each of the two conductors is hooked to the two sides of the ladder line. It now works better on 160m and still works on the other bands. It works better than my 45' -90' OCF dipole (commercial Fritzel) on 80m-10m.
I transmit and receive on it.

(For some reason I haven't received the original question emails. Had to go on the web to see them.)

I recall some questions in the past about large multi-turn loops, and finding very little written about them. I recall an answer to an earlier inquiry stating that they don't work.

Two notes I wish to add to that:

(1) I tried modeling a large multi-turn loop in NEC a while back (where "large" means more than 1/10 wavelength total wire) and it did not look good at all. Of course NEC can have problems, so I'm not saying it is a 100% accurate indication of performance.

(2) Multi-turn loops work when they are small because the currents are pretty much the same (in-phase) in each turn, so you have each of the turns reinforcing one another. But if you try to make a full wavelength skywire out of two half-wavelength loops, that doesn't hold. The current reverses polarity (or phase) on the other half, so you have the two turns essentially fighting one another. The radiated field from each turn cancels the field from the other turn.

That may explain why Tom's loop was poor on 160. But on multiples of that frequency, each turn is a full wavelength delayed from the other turn, so they are back in-phase again, and they reinforce. But not on 160m.

I described this in terms of transmitting, but remember that reciprocity holds; so if an antenna sucks for TX, it also sucks for RX.

For a receive loop on HF, I wouldn't think it matters if it's "too short" with only one turn. It'll work anyway. You don't need it to be resonant, unless you need to match to it, to transmit.

Regards,
Andy

Well Cebik has info about multiturn loops.
However, you are about the same circumference as the renown 88 ft all band dipole.
Perhaps consider putting your 94 foot loop with a insulator opposite the feedpoint,
use open wire or 450 ladder line feed to a tuner and enjoy 80 thru 17 meters.
Yes 15 to 10 also but I havent tried it. I have another 15 to 10 antennas.
You will just have a large one turn "cob-web" without all the wires.
Omni coverage pattern and relatively Stealth.
I have my 88 footer in a almost square and hung as a diamond vertical and it performs very well.
Fed at the top and supported from a 12 meter bamboo pole.

A multi turn skywire loop will be electrically longer as far resonance BUT
will not transmit or receive any better than a single wire one.

I’ve never made a loop before. Can get away without using a balun? I will be running 450 Ohm Ladder Line straight into a Palstar AT5K, then to the amp and then of course to the radio. I read about folks saying they use a 4:1 balun. I am thinking a 4:1 balun would be needed if I intended to use coax. Would I be ok without a balun?

Also, I am limited to a loop shape that will not be symmetrical. In order to accommodate my lot. If the legs are the same length, can it be nu-symmetrical?

I'm using a loop with ladder line and a 4-1 balun - works great. When I fed the loop with coax as a dedicated 40-meter loop I used a matching section and no balun. Now I use ladder line with balun and it works fine 40 meters and up. My loop is a lopsided mess - it's sure not symmetrical - and it works, it isn't as efficient but it's sure impressed me. I have it up very high - about 85 at the high point and it slopes down to about 40 feet - just did the best I could based on the trees in my yard.

I run a 160 meter loop drive by an SCG 239. I have a 15' ladder line from the SCG 239 to the antenna itself.

Tunes every band on MARS-ALE. Very good performance. Happy with set-up.

Would I get better performance with a BALUN?

You are correct in running the ladder line direct to the back of the tuner. I have found with coax and a balun, shape is more important. You will be OK with all ladder line.

I have a horizontal loop square in shape that is 300 feet long with each corner up at 35 feet. I have used a 4:1 and 1:1 BALUNS to RG-8X and RG-213U coax to my Kenwood TS-590S. In my case I found that the 1:1 BALUN worked better than the 4:1 BALUN between 160-6 meters as far as RFI in the shack and matching capability of the built in antenna tuner in the TS-590S.

But I have found that matching was easier with no RFI in the radio shack by bringing 40 feet of 300 ohm window line into the radio shack to either a Palstar BT-1500A or MFJ-974HB balanced antenna tuner. I mostly use the MFJ-974HB more than the Palstar BT-1500A because I know longer use an amplifier and I found the MFJ-974B to have a wider matching range.

Update.... I put up a 300' loop yesterday. It runs through branches and is not symmetrical. I used 450 Ohm ladder line straight to the tuner. I am very surprised that it works so well, given the way I was forced to go through branches and all. I understand it's not long enough for 160m. But I tuned up there and gave it a try. It worked. I was able to tune it flat and have a qso from Atlanta to Pittsburgh with a good signal report. If I can get this antenna in the open, perhaps it will do even better.

thanks for the info guys.

4411. Balun for horizontal loop

Yahoo group: SkyWires
Date: 2014-08-05 03:25:50 UTC
From: k9sqg@...
Topic: 4411 Message: 4411

While not an expert on the topic, I've been experimenting with horizontal loop antennas for over 25 years. As to feeding the loop, I believe there are two important considerations when trying to decide how to feed the loop in terms of open wire line or window line, and the use of a balun. These are based upon my experimental findings and not a theoretical analysis; I leave that to the experts.

The first consideration is whether the loop will be used for monoband use or whether multi-band use is desired. For single band use, feeding the antenna with 300 ohm transmitting twinlead is a better choice than 450 ohm or 600 ohm line. A balanced tuner like the Johnson/Nye KW Matchbox or the Palstar BT-1500A works quite well. The antenna itself, if resonant on the fundamental frequency or close to it, will have a resistive component of approximately 120 ohms. If one desires to use a balun, to get coax into the shack or for other reasons, a 4:1 balun will bring the resistive component down to 30 ohms and most tuners are better at matching values 50 ohms and above much easier than values below that; this is a gross generalization. While a 4:1 current balun might work in a particular installation, why not just use a 1:1 balun since it is a better choice?

If a loop is used for multiband operation, things change dramatically. By multiband I'm referring to frequencies above the fundamental frequency of the loop; I've had very poor luck going much lower in frequency than the fundamental in spite of what some have reported and find that my 80 m loop will just not load anywhere near 160 meters. For multiband use, deciding the type of feedline really depends on the specific bands of interest and the impedance of the antenna for those respective bands; both the resistive and reactive components are relevant. Bringing the 300 ohm or 450 ohm line into the shack gives quite a bit of flexibility and have had no trouble with multiband performance of my 80 meter horizontal loop when using a balanced tuner in the shack. If one desires to use a balun at some point, and then use coax to the tuner, then it behooves one to measure the terminal impedance of the antenna, or where the balun will be inserted, and see whether a 1:1 or 4:1 balun would be appropriate. I don't subscribe to the notion that a 1:1 or a 4:1 will work for multiband operation in any and all applications. One person's experiences might not work for somebody else due to site specifics of a particular configuration.

My main reason for using a horizontal loop is due to low cost and the reduction in noise; on 40 meters, my 40 m horizontal loop had a two (2) S-unit reduction in noise compared to a 1/4 wave vertical antenna using an A-B comparison based upon almost 400 contacts or listening sessions.

As a side note, as an experiment I installed a 1:1 DX Engineering current balun about midway between my 40 meter horizontal loop at 14 ft high and the shack, with the transition being to RG-8U coax. Antenna still works fine and no dramatic difference in performance except maybe a little less RF in the shack, hi hi. With this NVIS (?) antenna at night, I have easily broken pileups into Italy, Bulgaria, etc. but I prefer swap net and technical net operations over DX.

Those are my experiences and perspectives. Hopefully they might benefit some readers. Too, I'd like to learn from your experiences as well.

Thanks for reading the posting.

I agree with Evan about a loop and on some bands it might need a 1:1 while on others a 4:1 would be better using the loop on different bands. You can make your own switchable balun and have 1:1 or 4:1 with one current balun. It can be made with one large torrid, or two smaller ones or two rods, Here is a picture of mine final build. Mine sits on top of my tuner with a short run of coax to tunner.

Using 574 feet of insulated wire I use no balun on 160m and 80m. And use a 4:1 balun on 40m through 10m. A tuner is always needed to get back into 160. But the digital portion of the rest of the band's seams to line up pretty good, without a tuner at some locations. The loop is primarily used for camping and field day and has been configured many ways at different heights. Part of my "to go box" in the Grumman is the spool of wire, baling twine to hold up the wire, a fishing pole to reel the baling twine up over the tree limbs, and a bow and arrow to get the fishing line over the tree limbs. I prefer the fishing arrows as they weigh more, they already have a hole in them for string, and the barb removes easily.

Topic: 4414 Message: 4415

Jay,

Well, first of all, you might want to look at some of the plots from the antenna models to see what you get for a 1 WL loop versus a 2 WL loop. You have to go to the third or fourth harmonic of the fundamental to get a "dramatic" reduction in radiation angle. You'll see it, for example, when using an 80 m horizontal loop on 20 or 15 meters. But wait (time for that infomertial)!!! There is no such thing as a free lunch, here or elsewhere. While you will see a lowering of radiation angle, the price you pay can be seen in the radiation patterns. On the fundamental, you'll have a basically omnidirectional pattern but, as you go higher and higher in frequency, you start developing deep nulls in the azimuth pattern.

In theory, yes, a 2 wl loop might work marginally better on 160 meters but you're not going to see a dramatic difference for working DX. Let me give you an approximate analogy. I have two horizontal loops. One is a 40 m variant at about 15 ft high, and the other is an 80 m variant about 25-40 ft high depending on which corner you're looking at. On 40 m I often switch between the two antennas and see how they compare for various propagation conditions. Sometimes the 40 m antenna is better. Sometimes the 80 m antenna is better. And sometimes they are both equal. In some cases, during poor propagation, and further out, the 80 m loop is slightly better than the 40m loop. BUT the results are not large nor consistent. But using the 80 m loop on 20 or 15 meters, that's a different story.

Don't be worried about resonance of a loop. I did some experiments on 40 and 80 meters and varied the lengths from resonance by as much as 5-10 ft, shortening or lengthening. To be hones, I found my tuner settings changed a bit, but performance changes could not be seen on the air.

To me, I'd doubt that you would see any difference between a 1 wl and a 2 wl loop on 160 meters. But, I'm not an expert, and I only have my own observations/tests to rely on. I'm sure some of the experts can provide much better guidance than I can. Please keep the group informed so we can all learn from your experiences.

73,

Evan, K9SQG

Well yesterday was the day... The G5RV came down and the 2wl loop went up. So you can blame me for the horrible geomag storms that took place twice yesterday... The Loop is just over 1000 feet with 80% of it at near 100 feet high and one corner near 70 feet high. My legs are 200x300 , I used 3 inch garage door pulleys from Home Depot. The feed point is 40-55 feet of 450 ohm ladder line into a DX Engineering 10kw 1:1 balun and then about 10 feet of LMR400 coax to the Palstar AT5K. I could hardly believe it when I tuned to 1.825 and the swr was 1.1... Whats the odds , and seems to work and tune fine on all the other bands also. It's very quiet compared to the G5RV and maybe because the feed point is now 50 feet behind the house instead of the g4rv it was in the front of the house near the power lines. I'll play with it for awhile here and report again , but thanks to all who provided info for me...

Jay,

Glad you had such good luck with your loop. I envy the size and height. I've been using horizontal loops for over 20 years and am quite pleased with them as well.

Not sure I would have used garage door pulleys though. Why? The ones I looked at years ago are not designed for outdoor service and eventually the rain, snow, and ice will do a number on the lubricant. In all my years of experimentation I have found that the Harken brand of sailboat pulleys work great. They have stainless steel sides, and the pulley and bearings are made of Lexan and are resistent to UV. Not sure what the life is but the ones I have up right now have been there for over 10 years and show no sign of deterioration.

Please keep the group informed of your experiences. We'd all like to learn and be encouraged.

73,

Evan, K9SQG

Evan , I'm not sure on the life... But the ones they sell now are 100% Galvanized and I used a good marine grade lubricant on them. I couldn't find anything close to 3 inch except for the garage door ones. Will see how they weather... It's no big deal for me to drop the loop , it totally open inside of the loop (all mowed grass) so no obstructions to work around. I have a sat picture of the layout on my QRZ webpage... So far it is kicking but on all bands...

4419. Delta Loop questions

Yahoo group: SkyWires
Date: 2014-09-12 13:23:06 UTC
From: i8yomama@...
Topic: 4419 Message: 4419

I am going to try a Delta Loop. I started looking at intenet sites on measurements and such. When I built my 300' horizontal loop, I had two legs that were separated by an insulator directly opposite of the feed point. The diagrams shown for delta loops don't show two legs. it looks as if its one piece of wire going all the way around and back to the feed point. Can anyone give me some insight on this?

Also, I will be using 450 Ohm twin lead. I have not seen any info on Delta loops with ladder line. So, that could effect the measurements? Or maybe not. Any info would be very helpful to me.

Thanks,

Kirk / WT4P

Topic: 4419 Message: 4420

Yes, the delta loop is a continuous wire around the delta.
You can mount it apex up using one support pole with
horizontal near ground or apex down with horizontal high
and supported by 2 poles.
It can be fed at the center of the horizontal run or at the
apex for horizontal polarization. Fed at a corner will give
more vertical polarization. For true vertical it should be fed
1/4 wave down the sloping wire from the apex.

Fed with coax it is usually a one band antenna and the
loop length is resonant on that band. Length is between
1020 and 1040 divided bt frequency in MHz.
Old formula, 1005 divided by freq, for quad loops has been
wrong for 60 years. Proximity to ground, surrounding objects
and other factors will affect resonance.

Fed with open wire parallel feedline and a tuner at the shack
it can operate multibands. Actually, many install an auto-tuner
at the feed point for best operation all bands.

It can be installed horizontal and operated like any horizontal loop.
There are hundreds of different installations on the web.
If you want more info just ask.

Kirk and other enthusiasts,

In actuality, your antenna is a bent dipole and thus would perform differently than a true loop. That insulator opposite the feed point should not be there if one wants a true loop with the respective performance characteristics. The same would hold true if you open a delta loop and put an insulator opposite the feedpoint; it will perform differently.

Not sure how to answer your questions since there seems to be interest in loops as well as bent dipoles and not sure which you want to pursue.

Ladder line and window line are, well, basically feedlines and with a properly designed (balanced) antenna they should not radiate; hence that should not affect the dimensions of the antenna itself. Ladder line is very useful for multi-band antennas due to the low loss under high SWR conditions that accompany multi-band situations.

There is a lot of information on the Internet about these antennas, and some of it is true, while some of it is myth. Not sure what else to say at this time because I'm not sure if your interest is in loop antennas or bent dipoles in the shape of a loop. Much information is available on both antenna configurations, especially the works by L. B. Cebik, W4RNL (SK).

Please keep the group informed of your experiments so we all can learn.

From: Richard Schmuke
Topic: 4419 Message: 4422
Attachments: 2 described; binary payloads are missing from this source WARC

I have used a horizontal delta loop for a few years and like it. I had a 80M size loop and this year expanded it to a 160 size loop. I took into consideration on how many contacts I would make on each band and 40M won out so the antenna is adjusted to a good SWR in the middle of the 40M band. A 160 size delta loop is about a 200 ohm antenna on 80 and 40M so I feed it with a homemade 4:1 balun and coax. The balun is adjusted to have a low SWR between 40 & 80. The antenna works fine on 80M, 160 is a very wide band for antenna length so I take what I can get on 160 but my radio’s built in antenna tuner does not complain. My loops are one piece of wire, no insulator at the far point, that is a different antenna. On 20 and up I use a hex beam but the delta can do all well 160 thru 6 except no too good on 30M.

You might have better luck with ladder line feed on the higher bands because my balun falls of as the frequency increases, on the other hand more tuner adjustments with ladder line if you move around a lot as I do.

I use a Delta Loop antenna and that antenna i working very well.
Using 83,5 meter wire / in 3 leggs. In 1 corner I use a Balun 1:2 and from there 52 Ohm Koax cable
to my Palstar Automatic Tuner and then to the radio.
With that installation I work all bands, no problem.
I know Ham´s there use a 1:4 Balun.
My loop is only 10 meter over the ground.

Good Info guys. I will take down the bent dipole (thanks W4RNL) I am going to put up a true loop. Perhaps I can get to it next month. I'll post the any difference that I notice between the two antennas. I will make a delta loop this month, as it is easier to install. Thanks again to all that answered.

What I have found to be a very useful characteristic of a loop is that it reduces atmospheric and local noise by 1-2 S units compared to a 1/4 wave vertical on 40 meters based upon my tests. That can make all the difference when copying weak stations or when QRM/QRN are present. To me, absolute signal strength readings are not as important as signal to noise ratio. In contrast, a bent dipole in a loop configuration seems to lack this trait to a significant degree.

Because I work multiple bands, I found that window line (either 450 ohm or 300 ohm transmitting twinlead) work out quite well for me. My XYL prefers the lower visual cross section of 300 ohm transmitting twinlead, hi hi. After some analysis, I determined that a balun at the feedpoint would be problematic. Why? For my antennas and the bands of interest, I could not find a balun (1:1, 2:1, or 4:1) where the resulting ratio would be reasonable for all bands. By using window line (300 ohm transmitting twinlead) I avoid the complications and my tuner in the shack is quite happy. For those that prefer to use coax, other alternatives must be pursued.

From: Thomas W4HM
Topic: 4419 Message: 4426

Kirk,

I use a 300 foot long square in shape (not a delta loop) set up in the horizontal plane with each leg 75 feet long and each corner 35 feet up in oak trees, fed with 40 feet of 300 ohm window line to an MFJ-974HB balanced antenna tuner. It's a high angle radiator on 80 and 60 meters but becomes a decent DX antenna on 40 and 30 meters and a darned good DX antenna on 30-6 meters.

At first I tried a 300 foot long 3 sided delta loop also in the horizontal plane. It was fed with 40 feet of 450 ohm window line to a Palstar BT-1500A balanced antenna tuner. Because of nulls the delta loop did not perform as well in certain directions especially on the higher bands of 12, 10 and 6 meters. But the square loop has no noticeable nulls.

But of course every location is different as far as soil type and moisture content, nearby trees, buildings, power lines and of course other antennas. So for you you may not notice any nulls in a delta loop.

As far as the insulator opposite the feed point, by doing that you are not running a true loop but a bent dipole that would not work as well as a straight dipole would or square or delta loop. Also your bent dipole picks up more noise as compared to the closed loops.

By the way I do have a web page published on the square loop at
http://www.wcflunatall.com/w4hm15.htm

4428. Help! opinions please on delta loop balun

Yahoo group: SkyWires
Date: 2014-10-25 10:57:18 UTC
From: m6mrp@...
Topic: 4428 Message: 4428

Ok I will start by saying this all started when I started looking for a better match for my delta loop other than the 4:1 balun (this was a purchased loop kit) silly mistake as it was nasty inside wound with household table lamp twin flex still in its outer covering! and why use a 4:1 balun for an antenna which is "around" 125 ohms not 200 ohms which is 4:1 therefore 2:1 or even better 2.5 to 1 is the required target.
I am using a large verticaly mounted single turn multi band wire delta, corner fed due to a nasty local noise problem from a neighbors cheap 50 inch plasma TV which even wipes out my FT51r VHF handy when outside his house, swinging the loop on its axis I can find a sweet spot to null out the noise down to s5 from s9+ then my amazing BHI noise away gizmo does the rest, that has to be the best money my xyl has ever spent on me! I will never part with it.

As I will never pay for another sealed black box balun with only blind faith to go on the search began.
There is the talented balun by AG6IF which has good reports but is air core not what I am after.
Then I found an interesting web post about a trifilar wound 2.5 to 1 balun on a single toroid (not binocular) but this had 2 x 10 turns and 1 x 12.5 turns?
Now being new to all this toroid winding stuff I put my head on the block and brought the concept of a half turn up at my local radio club, needless to say I should be burned at the steak for witchcraft or voodoo for even mentioning such a thing but it is shown in the diagram in PDF here:-
1:2.5 Balun for multiband Deltaloop by dxzone.com
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=29519

And a half turn is also very briefly shown by the RA EMC studies and Ofcom:-

[URL=http://s1119.photobucket.com/user/Nightlife1/media/cablechok_zps23eff579.gif.html][IMG]http://i1119.photobucket.com/albums/k625/Nightlife1/cablechok_zps23eff579.gif[/IMG][/URL]

[URL=http://s1119.photobucket.com/user/Nightlife1/media/1andahalfturns_zpsf87d32fd.gif.html][IMG]http://i1119.photobucket.com/albums/k625/Nightlife1/1andahalfturns_zpsf87d32fd.gif[/IMG][/URL]

I have my thoughts on a half turn on a toroid ring and can measure a half turn as can Earl VE3AB in his test windings using the same L/C meter as myself:-
Ferrite Toroid Cores and Test Station http://www.earlandrews.com/tortest.html

I am probably way off the mark but my take on it is that as the magnetic field totally surrounds the toroid and both axial and radial currents flow on the externals of the profile of the ring therefore all part windings must also be taken into consideration?

I do not want to start another argument like at the club but would be interested in other peoples opinions on this half turn issue.
Please if the images from my photobucket do not come up could a mod. correct the link.

Any input from you lads?

4429. Re: loop with coil??

Yahoo group: SkyWires
Date: 2014-10-25 11:06:42 UTC
From: m6mrp@...
Topic: 4391 Message: 4429

Hi Richard, I tried this at my last qth for 40m on a smaller loop, the diagram is easily found by a web search for the three band delta loop, it worked but I found the coil made the loop noisy which defeated my uses for a loop in the first place, I ended up removing the coil and using an inverted v for 40 and the once again quiet loop for 20m to 10m, your findings may differ?
good luck
Phil M6MRP

From: Rich Schmuke
Topic: 4428 Message: 4430

This is just my outlook, I am sure many "ex-spurts" will say I am wrong.
I have also used a 2.5:1 on a single band delta loop antenna as it is a
100 ohm antenna but at multiple frequencies it is a 200 ohm antenna, then I
use a 4:1 balun.
On my main delta 160 size loop I use a 4:1 duel rod Guanella , ref book by
Jerry Sevick, W2FMI.
Balun and antenna adjusted to low SWR at the center of the 40M band and
loop mainly used on the 3 lower bands. SWR is a little high on 160, but
fine on 80 & 40 because when used on the multiple frequencies it is a 200
ohm antenna. I could double the size of the loop and help on 160 but I
would have to cut down more trees than this old back want to mess with.

Here is a picture of my path I cut for the single loop.
http://s1102.photobucket.com/user/KD0ZZ/media/160%20Loop/trees010_zpse5180867.jpg.html

FYI a ex-spurt is , ex is a has been and a spurt is a drip under pressure

4431. Re: [SkyWires] Help! opinions please on delta loop balun

Yahoo group: SkyWires
Date: 2014-10-25 15:26:43 UTC
From: Evan Rolek
Topic: 4428 Message: 4431

I've found that feeding a multiband wire antenna with 300 ohm transmitting twinlead, 450 ohm window line, or 600 ohm open wire line, and using an antenna tuner in the shack greatly simplifies things for me...

Subject: Re: [SkyWires] Help! opinions please on delta loop balun

This is just my outlook, I am sure many "ex-spurts" will say I am wrong.
I have also used a 2.5:1 on a single band delta loop antenna as it is a 100 ohm antenna but at multiple frequencies it is a 200 ohm antenna, then I use a 4:1 balun.
On my main delta 160 size loop I use a 4:1 duel rod Guanella , ref book by Jerry Sevick, W2FMI.

Balun and antenna adjusted to low SWR at the center of the 40M band and loop mainly used on the 3 lower bands. SWR is a little high on 160, but fine on 80 & 40 because when used on the multiple frequencies it is a 200 ohm antenna. I could double the size of the loop and help on 160 but I would have to cut down more trees than this old back want to mess with.

Here is a picture of my path I cut for the single loop.
http://s1102.photobucket.com/user/KD0ZZ/media/160%20Loop/trees010_zpse5180867.jpg.html

FYI a ex-spurt is , ex is a has been and a spurt is a drip under pressure

On Sat, Oct 25, 2014 at 5:57 AM, m6mrp@... [SkyWires] <SkyWires@yahoogroups.com> wrote:

Ok I will start by saying this all started when I started looking for a better match for my delta loop other than the 4:1 balun (this was a purchased loop kit) silly mistake as it was nasty inside wound with household table lamp twin flex still in its outer covering! and why use a 4:1 balun for an antenna which is "around" 125 ohms not 200 ohms which is 4:1 therefore 2:1 or even better 2.5 to 1 is the required target.
I am using a large verticaly mounted single turn multi band wire delta, corner fed due to a nasty local noise problem from a neighbors cheap 50 inch plasma TV which even wipes out my FT51r VHF handy when outside his house, swinging the loop on its axis I can find a sweet spot to null out the noise down to s5 from s9+ then my amazing BHI noise away gizmo does the rest, that has to be the best money my xyl has ever spent on me! I will never part with it.

As I will never pay for another sealed black box balun with only blind faith to go on the search began.
There is the talented balun by AG6IF which has good reports but is air core not what I am

after.
Then I found an interesting web post about a trifilar wound 2.5 to 1 balun on a single toroid (not binocular) but this had 2 x 10 turns and 1 x 12.5 turns?
Now being new to all this toroid winding stuff I put my head on the block and brought the concept of a half turn up at my local radio club, needless to say I should be burned at the steak for witchcraft or voodoo for even mentioning such a thing but it is shown in the diagram in PDF here:-
1:2.5 Balun for multiband Deltaloop by dxzone.com

And a half turn is also very briefly shown by the RA EMC studies and Ofcom:-

[URL=http://s1119.photobucket.com/user/Nightlife1/media/cablechok_zps23eff579.gif.html][IMG]http://i1119.photobucket.com/albums/k625/Nightlife1/cablechok_zps23eff579.gif[/IMG][/URL]

[URL=http://s1119.photobucket.com/user/Nightlife1/media/1andahalfturns_zpsf87d32fd.gif.html][IMG]http://i1119.photobucket.com/albums/k625/Nightlife1/1andahalfturns_zpsf87d32fd.gif[/IMG][/URL]

I have my thoughts on a half turn on a toroid ring and can measure a half turn as can Earl VE3AB in his test windings using the same L/C meter as myself:-
Ferrite Toroid Cores and Test Station

I am probably way off the mark but my take on it is that as the magnetic field totally surrounds the toroid and both axial and radial currents flow on the externals of the profile of the ring therefore all part windings must also be taken into consideration?

I do not want to start another argument like at the club but would be interested in other peoples opinions on this half turn issue.
Please if the images from my photobucket do not come up could a mod. correct the link.

Any input from you lads?

From: abe
Topic: 4428 Message: 4432

Insulated wire (572 ft), 110 ft of 450 ohm window line, works for me. Its part of my mobile to go set up that works well at 8 ft or 120 ft, whatever the trees provide. It shows resistance about 1.7 MHz, 3.5 MHz, 7 MHz, and 14 MHz. A tuner is needed on 75 & 80 meter. When using the 4:1 air balun Ace has shared no tuner needed for digital on 20 & 40 meter. With a tuner all parts of all HF ham bands are usable.

Hoping the 2.5:1 balun will let me work without a tuner on 80 meter, thank you for sharing. Abe K7ABE

Connected by DROID on Verizon Wireless

I just use ladder line and avoid the issue of baluns, coax and high losses. If I were using as a single frequency, and it was 100 ohms, then would use a 1/4 wave of 75 ohm to achieve matching. Then a 1:1 balun would work.

Since I use it at multiple frequencies, ladder line works fine and avoids a lot of issues.

When working with ladder line and many non balanced tuners a 4:1 balun is required, (sometimes inside the tuner) You can make a 4:1 or 1:1 switchable balun and install just before the tuner for the easy option of the best match.

That is very true if you have an unbalanced tuner. I am fortunate in that I have a balance tuner.

<SkyWires@yahoogroups.com> wrote:

Ok I will start by saying this all started when I started looking for a better match for my delta loop other than the 4:1 balun (this was a purchased loop kit) silly mistake as it was nasty inside wound with household table lamp twin flex still in its outer covering! and why use a 4:1 balun for an antenna which is "around" 125 ohms not 200 ohms which is 4:1 therefore 2:1 or even better 2.5 to 1 is the required target.
I am using a large verticaly mounted single turn multi band wire delta, corner fed due to a nasty local noise problem from a neighbors cheap 50 inch plasma TV which even wipes out my FT51r VHF handy when outside his house, swinging the loop on its axis I can find a sweet spot to null out the noise down to s5 from s9+ then my amazing BHI noise away gizmo does the rest, that has to be the best money my xyl has ever spent on me! I will never part with it.

As I will never pay for another sealed black box balun with only blind faith to go on the search began.
There is the talented balun by AG6IF which has good reports but is air core not what I am after.
Then I found an interesting web post about a trifilar wound 2.5 to 1 balun on a single toroid (not binocular) but this had 2 x 10 turns and 1 x 12.5 turns?
Now being new to all this toroid winding stuff I put my head on the block and brought the concept of a half turn up at my local radio club, needless to say I should be burned at the steak for witchcraft or voodoo for even mentioning such a thing but it is shown in the diagram in PDF here:-
1:2.5 <http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=29519> Balun for multiband Deltaloop by dxzone.com

And a half turn is also very briefly shown by the RA EMC studies and Ofcom:-

ok_zps23eff579.gif%5B/IMG%5D%5B/URL>]

[URL=http://s1119.photobucket.com/user/Nightlife1/media/1andahalfturns_zpsf87d32fd.gif.html][IMG]http://i1119.photobucket.com/albums/k625/Nightlife1/1andahalfturns_zpsf87d32fd.gif[/IMG][/URL
<http://s1119.photobucket.com/user/Nightlife1/media/1andahalfturns_zpsf87d32fd.gif.html%5D%5BIMG%5Dhttp:/i1119.photobucket.com/albums/k625/Nightlife1/1andahalfturns_zpsf87d32fd.gif%5B/IMG%5D%5B/URL>]

I have my thoughts on a half turn on a toroid ring and can measure a half turn as can Earl VE3AB in his test windings using the same L/C meter as myself:-
Ferrite <http://www.earlandrews.com/tortest.html> Toroid Cores and Test Station

I am probably way off the mark but my take on it is that as the magnetic field totally surrounds the toroid and both axial and radial currents flow on the externals of the profile of the ring therefore all part windings must also be taken into consideration?

I do not want to start another argument like at the club but would be interested in other peoples opinions on this half turn issue.
Please if the images from my photobucket do not come up could a mod. correct the link.

Any input from you lads?

Cheers lads lots to mull over there and lots of it helps me understand what I have seen in my trials with the delta loop, saying that Im no "ex-splurt" yet lol
As for the feed line instead of coax and keeping it balanced I did try that, (well sort of) my loop is in in a big loft above so I managed to get a plastic pipe down through the ceiling just below the feed point direct down into my small shack (large broom cupboard) so dropping twin feed down was easy but my tuner is not a "real tuner" its an MFJ945E and yes I know what MFJ stands for but after you swap out all the bad grade components on the metering circuit and re-calibrate its not that bad for what it is, and hey beggars cant be choosers when you are just starting out and get the hand-me-downs for cheap or for free! Next thing to build is a real BLT and I even have most the bits in hand from friendly donations, the last twin feeder attempt had to be terminated (due to the 945E only taking PL259 plugs) with a home brew attempt of the talented balun which didnt seem to help then a 4:1 balun which gave me a good match on some bands but not others which were problematic to tune but this is not surprising if the loop presents different ohms on different bands as you say.

Another question for you guys, would a 1:1 toroid common mode choke at either end of the coax be of any use on a delta loop? I only ask as I have noticed that a few of the big name balun makers are boxing up a 1:1 choke with their 2.5:1 or 2:1 loop baluns, and a few old pdf,s Ive read about loops say that when using coax it should be isolated from the loop?

Things are just not right here! I have just finished a magnetic loop build from a salvaged ali cycle wheel with two variable caps 1 for 10m to 20m and another bigger one for 40m and 80m it tunes all bands nicely with LEDs to show when its at max tune, this mag loop is hearing stations that my big delta loop in the loft does not hear even when on the same axis which is the null in the local noise? I have even tried the little mag loop in the loft on the same coax as the big loop and its ears are much better?

The saga continues.

4438. delta loop balun new results

Yahoo group: SkyWires
Date: 2014-10-29 14:04:30 UTC
From: m6mrp@...
Topic: 4428 Message: 4438

Hi guys, the xyl was out for the day so I decided to try a couple of CM 1:1 chokes on my loft mounted delta loop which was not working as it should, had a tune about on the FT817nd on the bicycle wheel mag loop and found IZ4NPE working 21.275MHz with his usual very strong signal here 5/9+ as clear as can be and I was hearing many of his outside EU contacts so all is well with that setup, moved over to the loft delta loop fed with about 10m of mini 8 coax down to the MFJ945E and my FT840 not so good! he was about 5/5 and in the noise and I was hearing none of his outside EU contacts?

After messing about with toroid fed mag loops for a while I had a couple of type 43 Ni/Zn cores lying about, one is about 1inch and one about 1 1/2 inches across and deeper so I quickly wrapped them as CM chokes and checked for any transformation resulting in 8 passes of mini RG174/U on the 1 inch and 7 passes of the same thin coax on the larger toroid, stuck the smaller one at the tuner input and nothing changed with the signals but the tuning changed, it became much smoother to tune and all bands are now within 3 notches on the 945E instead as being spread all over the dial?

Climbed into the loft with the other CM choke in pocket (not easy when you need a new knee and are having steroid injection into your hip to keep it going as long as possible) parted the delta feed point connection and hooked up the choke and instantly the delta loop came alive! even from in the loft I could hear the dramatic change in reception, the noise level had dropped again now S3 from S5 (inverted V dipole was S9+) and voices are very clear and strong.

All in all I have answered my own question, yes it is a benefit to add a couple of 1:1 CM chokes to a delta loop when feeding with coax and it makes tuning with a basic tuner (not a real BLT) very easy without any other baluns fitted.

Next thing to do is to purchase a couple of matching type 43 Ni/Zn toroidials big enough to make the chokes with some decent PTFE coax and encase them in plastic boxes with N type sockets.

I would never have believed a couple of 1:1 CM chokes could make such a vast difference so I am really glad I tried it, it just goes to show how coaxial feed can mess up what we all know is a great antenna.

73
and thanks for all the input.
Phil M6MRP

Dear Phil, Thanks for sharing the results of your A/B tests using the common mode chokes. You clearly demonstrate the benefit of this method to eliminate common mode noise/radiation on our antenna/transmission line systems. In Zip Cord Transmission Lines and Baluns http://www.qsl.net/kp4md/zipcord.htm#balun

http://www.qsl.net/kp4md/zipcord.htm#balun

Zip Cord Transmission Lines and Baluns http://www.qsl.net/kp4md/zipcord.htm#balun This article describes an application of a low cost speaker wire zip cord with common mode current chokes as an effective high frequency transmission line.

View on www.qsl.net http://www.qsl.net/kp4md/zipcord.htm#balun
Preview by Yahoo

I shared impedance measurements at the loop feed point and at the antenna tuning unit to explain the rationale of using simple common mode chokes on the transmission line . This can be accomplished with ferrites as you have done, or by winding an "Ugly balun" on a length of your coaxial cable.

In their articles Common-Mode Chokes http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf9 and A Ham's Guide to RFI, Ferrites, Baluns, and Audio Interfacing http://www.audiosystemsgroup.com/RFI-Ham.pdf10 Counselman and Brown discuss the use of common mode chokes to:

reduce undesired common mode radiation and noise pickup on transmission lines; serve as a transition between balanced and unbalanced sources and loads if needed; and, be configured to provide impedance transformation, if needed.When used to transition between a balanced load and an unbalanced source and vice versa, as Guanella11 described, they are sometimes called current baluns or choke baluns.
Figure 37 in reference 1 shows the feed point impedance variation between 80 and 350 ohms at the resonance frequencies of 7, 14, 21 and 28 MHz, presenting corresponding VSWRs of 1.3:1 to 3:1 to the 114 ohm zip cord. 4:1 impedance transformation at that point would increase the VSWR to 5.7:1 at 7 MHz; therefore no impedance transformation in needed at the feed point. Neither is a balun needed as both the antenna and zip cord are balanced. Therefore, a simple common mode choke is used there to reduce common mode radiation and noise. Likewise, figure 54 in reference 1 shows the impedance at resonance frequencies measured at the transmitter end of the 51 foot transmission line varying between 45 and 120 ohms. Therefore, a simple common mode choke would serve to reduce common mode noise and to transition the unbalanced antenna tuning unit (ATU) to the balanced zip cord, leaving the ATU to perform the impedance transformation to the 50 ohm radio.

Though not for everybody, I use either a Johnson Kilowatt Matchbox or a Palstar BT-1500A balanced tuner to solve all my multiband matching issues with my 40 m and 80 m horizontal loops. The Matchbox doesn't need a balun and it has no direct connection between the primary and secondary of the coil thus reducing the influence of static buildup on the front end of my transceiver.

I am using a MFJ Versa Tuner V, which I think grounds one side (I think). I have had no issues using the tuner or a loop on multiple bands. I think it is a lot easier and lower losses than coax and a lot more flexible.

Balanced tuners are not rare at all. The 275 watt Johnson Matchbox, the Kilowatt Matchbox, the Nye versions of the Matchboxes, the Palstar BT-1500A, etc. etc. are available on Ebay almost all the time. I have several of these that I use quite successfully. Building a balanced tuner is quite easy as well.

Yes but the Palstar is the only one in current production. True balanced tuners are rare in the current market. I'm pretty sure the MFJ Versa Tuner Scott mentioned has a balun inside it, so he isn't really avoiding balun "issues".

Now, is there any real difference between a balanced tuner and an unbalanced one with a balun? IDK. Personally I do tend to trust big open coils and wide spaced capacitors over cramped toroids, but that may be unfounded.

Ken and other loop enthusiasts,

Yes, there is a big difference between an unbalanced tuner with balun and a true balanced tuner. Most tuners with baluns have the balun at the end connecting to the antenna. As a result, the balun is likely subjected to a very wide range of impedances both in terms of resistive components and reactive components; this is not the friendliest environment for a balun and it is likely that some conditions will be outside the matching range of the balun resulting in heating, voltage spikes, etc. which under some circumstances will destroy the balun. If you're lucky, the core will saturate and there will be no damage but at higher power levels, you might not be as lucky. An air core coil won't saturate in this way, thus the popularity of the Johnson/Nye Matchboxes. This is not to say all toroids are bad but, subjected to the wrong conditions outside the design parameters, they can and do fail.

Another reason I prefer air coils to toroids for tuners is that the toroids have a fixed ratio, e.g. 1:1, 2:1, 4:1, 9:1, etc. and multiband applications will often produce conditions where the ratio is right on for one band, too high for others, and yet too low for others. One size will not fit all. The Matchbox design has a wider matching range I've found. Yes, some will complain that the Matchbox has a "narrow" matching range, but I'm not sure what they really mean. Why? Well, most open wire or window line, multiband antennas have a high resistive and/or reactive component, exactly what the Matchbox was designed for. So if you have, for example, impedances below 50 ohms then you're starting to operate the tuner outside the design range. If I remember correctly, the manual states a matching range of something like 50-2,000 ohms and I've never had an antenna outside that range so I'm pleased with the Matchbox as well as the BT-1500A. Like anything, when you subject a piece of equipment to conditions outside the design parameters you run into problems but, for me, I've found the tuners that work best for me. Your mieage might vary...

73,

Evan, K9SQG

Hi Guys,

Kc8hps Bryan here,

Im disabled and I need a hand modeling a simple wire antenna to see the radiation pattern and swr
for 2 meters at 145 mhz.

Ive had 2 strokes and over 175 seizures and my ability to understand this program just escapes me
it frustrates me to no end.

What I need is basically a Slim jim antenna that has a second element coming off of it to the right at the gap going back up as a 1/2 wave in phase with the other 2 1/2 waves that are already in phase that is all.

Thanks if anyone is able to help. My direct email is in my profile at qrz.com to avoid spam

thank you, Bryan kc8hps

Would help me to know, best measurement for twin lead spreader, thinking 3 inches for spreader lengths , Distance between spreaders ? 18 " ? , using 12ga, Full wave loop 160meters, thinking around 508 ft but have enough to go longer , distance from loop for Feed twin lead is about 110ft , , want to know best length for Feed , only Twin lead into Heath SA2060A has built in Balun, no Coax will be used . Height will be about 42-46ft , have all ready and two holes dug and filled , just would like any numbers that can be shared with this info.

Appreciate any Chime in on this , THank you , W5HEH 73s, AJ

AJ,

Hard to know since proposed use of antenna is unknown. For example, 160 M monoband or multiband? This will determine the range of impedances that will be encountered which in turn will suggest the spacing of the feeders. It is likely to be non-critical since the loss will be small in most cases. Physical appearance, wind/ice loading, etc. will suggest what type of spacing might offer advantages.

In my loops, 40 M and 80 M horizontal loops, I switched from 450 ohm window line to 300 ohm transmitting twinlead to reduce the visual cross section, for the xyl. Both antennas continue to work well, 40 M as a monobander, and the 80 M loop as a multibander.

Spreaders are readily available from 73CNC, I believe, and they are UV resistant, Lexan (?) black for low visibility and won't break if dropped like glass ones, etc.

Subject: [SkyWires] need answers on Feed spreader distance and length

Would help me to know, best measurement for twin lead spreader, thinking 3 inches for spreader lengths , Distance between spreaders ? 18 " ? , using 12ga, Full wave loop 160meters, thinking around 508 ft but have enough to go longer , distance from loop for Feed twin lead is about 110ft , , want to know best length for Feed , only Twin lead into Heath SA2060A has built in Balun, no Coax will be used . Height will be about 42-46ft , have all ready and two holes dug and filled , just would like any numbers that can be shared with this info.

Appreciate any Chime in on this , THank you , W5HEH 73s, AJ

In Oregon, on one city lot, I still use an 80 40 meter inverted V fan (it gives me 10-80m). Following is my main antenna for field days and camping, it has went up and down many times at different heights and in different configurations with very similar results. I set my 160 loop up around 1.7MHz (best I remember about 574 ft of insulated 12ga wire). This gives me a pour match for 160m but a good match for the digital part of 10-80m. I remove a section of wire, maybe 50 feet, when I want to focus on 80 meter phone. It is fed with 110ft of 450 ohm ladder line. A 4:1 balun is used on 10 through 40 meter and no balun needed on 80 meter. Little or no tuning is needed for the digital portion of these bands. A good tuner is needed to make 160 usable.
Hope this is useful info,
Abe K7ABE

AJ,

Hard to know since proposed use of antenna is unknown. For example, 160 M monoband or multiband? This will determine the range of impedances that will be encountered which in turn will suggest the spacing of the feeders. It is likely to be non-critical since the loss will be small in most cases. Physical appearance, wind/ice loading, etc. will suggest what type of spacing might offer advantages.

In my loops, 40 M and 80 M horizontal loops, I switched from 450 ohm window line to 300 ohm transmitting twinlead to reduce the visual cross section, for the xyl. Both antennas continue to work well, 40 M as a monobander, and the 80 M loop as a multibander.

Spreaders are readily available from 73CNC, I believe, and they are UV resistant, Lexan (?) black for low visibility and won't break if dropped like glass ones, etc.

73,

Evan, K9SQG

Us non-city boys go to the local farm supply for ladder line insulators.
http://www.ruralking.com/agriculture/fencing-supplies/electric-fencing/electric-fence-insulators-acce/dare-4-tube-insulator-50-pieces-per-bag-1718.html
50 pc of 4" spacers for the high price of $4.99 , if the link does not
work go to Rural King, SKU # 070040553. You can cut them in half and have
a 100 PC's for 5 bucks and a few tie-wraps. A tie wrap around the wire and
then thru the insulator and your are done. Also dipole ends, 50 cents for
porcelain and 25 cents for UV resistant plastic.
There are several name brand supply stores with fence parts and all parts
are made for sun proof and good with electricity

Buy some "rozenclips" from amevo

They are use in green-houses to clamp a plant (tomato or roses or) to a wire

Works superb for making ladderline

Sigi, do you have a URL for the AMEVO company.?
The info in the foto does not reference a URL.
Also, SOTA in England has plastic laser cut spacers for open wire line.
I have samples on the way to Ecuador to test.
Thanks for the info

Sigi, they are great clips and you can get then for 3 size wires but the quantity and overseas shipping was a little high for me, good for you. I could not find them over here.

Interesting, I had not thought of using those for feedline spreaders.

What I've used is to cut up plastic clothes hangers into 3-1/2" sections (about 7 per hanger) and drill holes near the ends for the wires to go through. It works fine.

Evan, loop will be horizontal 160m multiband, used mostly on 40m , with full tank Tuner has Balun in it Heathkit 2060A , i live in Rural area , and no issues on Visual details , XYL has Her Hobbies that i help with, Milk Cows, Making Cheese, Chickens , Growing Food organic methods, so She understands , might grumble , but at our age it is common anyways ! lol. I am using 1/2inch pvc for spreading, so wanted 2 cents from all here on distance between each spreader and length of them as well . This hobby is making me more active , so we both get benefits having me more healthy coming into spring when we need to do a lot of Garden preparations . Putting up EMT conduit pipes , instead of towers , Trees here are just not lined up well and then would have to deal with movement in winds , i do have long OCF Flat top between two trees now , so far so good , 1st season. Got Back into Ham Radio this year, was Ham as a Teen in the 60s, landlord gave me permission to put up a Tower , still can't believe it , Friends helped me and my Dad helped with cement after we poured it .
THanks to all who are, and still commenting , will read all and use advice carefully, 73s to all , "AJ" W5HEH

Rich, wow OM , this is a great tip on electric fencing tube insulators for spreaders ! These make more sense than cutting up PVC pipes and they are black better UV resistance . Really appreciate it , hope others will benefit from this , maybe put up a pic in Files section . Thank you again, 73s, AJ W5HEH

ps link worked fine .

4462. Re: [SkyWires] need answers on Feed spreader distance and length

Yahoo group: SkyWires

From: Evan Rolek
Topic: 4452 Message: 4462

AJ,

Not being an antenna expert, I can only draw upon what research I've done and the test results that I have. A few comments are provided below.

I suspect the balun on you have on the tuner is on the output (antenna) side. This is problematic for multiband operation. Why? There will be a wide range of impedances presented to the balun. I'm assuming the balun is a 4:1 ratio, voltage style; however, the problems are there for any balun in that location. On the fundamental frequency, 160 M, the loop will have an impedance of around 110 ohms resistive, with some reactive component though not likely too high. A 4:1 balun will then transform that down to about 28 ohms, which might be below the capabilities of the tuner. Then, on other bands, one can see resistive components in the thousands of ohms and reactive components in the hundreds of ohms. Baluns have a limited impedance range over which they can operate properly. Outside that range, they heat up, develop high peak voltages, and experience high loss. A more efficient approach would be to use a balanced antenna tuner (Johnson Matchbox for 80-10, Palstar BT-1500A for 160-10, etc. etc.).

Hence, for multiband operation, no matter what feedline, balun, or tuner you use, there will be problems on one or more bands. Whether you operate those bands or not determines how lucky you are, hi hi. So the issue becomes one of optimizing the entire system for your particular needs. As a starting point, you could reference the modeling work of others (e.g. W4RNL website, the L. B. Cebik books published by MFJ, etc.) to find out what range of impedances you can expect to see for your installation. The Ho-Ho-HOPL articles by LB show the range of impedances for a horizontal loop at various frequencies. This in turn can then be used to select the type of window line or open wire line that best suits your needs. Many seem to rely on old wives' tales, hearsay, and emotion when picking feedlines with the 450 ohm window line and 600 ohm open wire choices being the most popular; but one size does not fill all. Too, any of the choices will work to varying degrees, it is just a matter of what's best, electrically, mechanically, and visual appearance for xyls, hi hi.

So then we come down to the tuner. If one has an "appropriate" tuner that is designed to handle a multiband antenna fed with "non-coax", then it can handle the impedance transformation and do so with low to reasonable loss. The tuners I use are the Johnson Kilowatt Matchbox, and the Palstar BT-1500A, which are best suited. However, for convenience, I've been known to use my Drake MN-2700 and even Millen 92200 (with external balun). The Johnson Matchbox can't have a saturated balun core because it uses air wound link coil arrangements; some say it has "limited" matching range but I've not had an antenna it couldn't match successfully. To assist with making a choice, there have been some review and test articles written in QST comparing the loss and matching range of various tuners. The ARRL "Antenna Tuner Book" specifically addresses the topic with some interesting test results.

Remember, perfect is the enemy of good enough. And the worst antenna and feedline will yield more enjoyment on the air than the best arrangement on paper. The approach I use is to select the best antenna, electrically for my purposes, and then modify the choice based

upon my site specifics (cost, space, xyl, etc.). And if one enjoys experimenting, trying multiple approaches can be fun. Besides it is good exercise, physically and mentally. I enjoy using my configuration, especially having a tuner in the shack to handle all the adjustments; feeding my 80 M horizontal loop as a top loaded vertical, fed against ground, works to my satisfaction on 160.

There are a lot of experts out there that can provide better guidance than I can and I hope they provide you with the input that you need.

73,

Evan

Evan, loop will be horizontal 160m multiband, used mostly on 40m , with full tank Tuner has Balun in it Heathkit 2060A , i live in Rural area , and no issues on Visual details , XYL has Her Hobbies that i help with, Milk Cows, Making Cheese, Chickens , Growing Food organic methods, so She understands , might grumble , but at our age it is common anyways ! lol. I am using 1/2inch pvc for spreading, so wanted 2 cents from all here on distance between each spreader and length of them as well . This hobby is making me more active , so we both get benefits having me more healthy coming into spring when we need to do a lot of Garden preparations . Putting up EMT conduit pipes , instead of towers , Trees here are just not lined up well and then would have to deal with movement in winds , i do have long OCF Flat top between two trees now , so far so good , 1st season. Got Back into Ham Radio this year, was Ham as a Teen in the 60s, landlord gave me permission to put up a Tower , still can't believe it , Friends helped me and my Dad helped with cement after we poured it .
THanks to all who are, and still commenting , will read all and use advice carefully, 73s to all , "AJ" W5HEH

And then ,of course, there is a trip to the beauty supply house for "perm Rods"These are the right length for about 600 ohms down to 300 ohms. They have multiple holes in them depending on the mfgr and I pick the dark grey or brown ..I could use pink ones I guess but I would be taking a lot of time explaining what they are. The box full I have now(grey) was purchased at a yard sale.I like them because the holes are all the same and after threading them on the wire a drop of super glue holds them in place.
I Think you will find that the length is relatively non critical I use about 55 feet spaced about 1inch and a half and # 18 wire to feed my summer QTH 160 loop on all bands including 6 meters. Loop is about 575 feet long and 30 to 60 feet high. Strictly for esthetics I use 60 feet of 300 Ohm window line to feed my 80 meter loop in the back yard of our winter QTH(in a subdivision) It is very low viz and keeps the neighbors and XYL happy. I have no trouble feeding it on any band from 80 to 6.I like this option because I don't have to cut anything and drill holes...HI

need answers on Feed spreader distance and length

Thu Dec 11, 2014 9:35 am (PST) . Posted by:

w5heh
Would help me to know, best measurement for twin lead spreader, thinking 3 inches for spreader lengths , Distance between spreaders ? 18 " ? , using 12ga, Full wave loop 160meters, thinking around 508 ft but have enough to go longer , distance from loop for Feed twin lead is about 110ft , , want to know best length for Feed , only Twin lead into Heath SA2060A has built in Balun, no Coax will be used . Height will be about 42-46ft , have all ready and two holes dug and filled , just would like any numbers that can be shared with this info.

Appreciate any Chime in on this , THank you , W5HEH 73s, AJ

AJ,

Hard to know since proposed use of antenna is unknown. For example, 160 M monoband or multiband? This will determine the range of impedances that will be encountered which in turn will suggest the spacing of the feeders. It is likely to be non-critical since the

loss will be small in most cases. Physical appearance, wind/ice loading, etc. will suggest what type of spacing might offer advantages.

In my loops, 40 M and 80 M horizontal loops, I switched from 450 ohm window line to 300 ohm transmitting twinlead to reduce the visual cross section, for the xyl. Both antennas continue to work well, 40 M as a monobander, and the 80 M loop as a multibander.

Spreaders are readily available from 73CNC, I believe, and they are UV resistant, Lexan (?) black for low visibility and won't break if dropped like glass ones, etc.

73,

Evan, K9SQG

"abe" abemitchell777
In Oregon, on one city lot, I still use an 80 40 meter inverted V fan (it gives me 10-80m). Following is my main antenna for field days and camping, it has went up and down many times at different heights and in different configurations with very similar results. I set my 160 loop up around 1.7MHz (best I remember about 574 ft of insulated 12ga wire). This gives me a pour match for 160m but a good match for the digital part of 10-80m. I remove a section of wire, maybe 50 feet, when I want to focus on 80 meter phone. It is fed with 110ft of 450 ohm ladder line. A 4:1 balun is used on 10 through 40 meter and no balun needed on 80 meter. Little or no tuning is needed for the digital portion of these bands. A good tuner is needed to make 160 usable.
Hope this is useful info,
Abe K7ABE

Connected by DROID on Verizon Wireless

Us non-city boys go to the local farm supply for ladder line insulators.
http://www.ruralking.com/agriculture/fencing-supplies/electric-fencing/electric-fence-insulators-acce/dare-4-tube-insulator-50-pieces-per-bag-1718.html
50 pc of 4" spacers for the high price of $4.99 , if the link does not work go to Rural King, SKU # 070040553. You can cut them in half and have a 100 PC's for 5 bucks and a few tie-wraps. A tie wrap around the wire and then thru the insulator and your are done. Also dipole ends, 50 cents for

porcelain and 25 cents for UV resistant plastic.
There are several name brand supply stores with fence parts and all parts
are made for sun proof and good with electricity

Buy some "rozenclips" from amevo

They are use in green-houses to clamp a plant (tomato or roses or) to a wire

Works superb for making ladderline

Sigi, do you have a URL for the AMEVO company.?
The info in the foto does not reference a URL.
Also, SOTA in England has plastic laser cut spacers for open wire line.
I have samples on the way to Ecuador to test.
Thanks for the info

Sigi, they are great clips and you can get then for 3 size wires but the
quantity and overseas shipping was a little high for me, good for you. I
could not find them over here.

"Ken" wa8jxm
Interesting, I had not thought of using those for feedline spreaders.

What I've used is to cut up plastic clothes hangers into 3-1/2" sections (about 7 per hanger) and drill holes near the ends for the wires to go through. It works fine.

From: Evan Rolek
Topic: 4463 Message: 4464

As a side note, with window line, 450 ohm or 300 ohm transmitting twinlead, one can increase the hole size to reduce the effects of rain, snow, and ice on the feedline. I use a "siding notcher", bought at either Lowe's or Home Depot I believe, found in the section of the store that sells plastic and/or aluminum siding, molding, etc.

And then ,of course, there is a trip to the beauty supply house for "perm Rods"
These are the right length for about 600 ohms down to 300 ohms. They have multiple holes in them depending on the mfgr and I pick the dark grey or brown ..I could use pink ones I guess but I would be taking a lot of time explaining what they are. The box full I have now(grey) was purchased at a yard sale.I like them because the holes are all the same and after threading them on the wire a drop of super glue holds them in place.

I Think you will find that the length is relatively non critical I use about 55 feet spaced about 1inch and a half and # 18 wire to feed my summer QTH 160 loop on all bands including 6 meters. Loop is about 575 feet long and 30 to 60 feet high.
Strictly for esthetics I use 60 feet of 300 Ohm window line to feed my 80 meter loop in the back yard of our winter QTH(in a subdivision) It is very low viz and keeps the neighbors and XYL happy. I have no trouble feeding it on any band from 80 to 6.
I like this option because I don't have to cut anything and drill holes...HI

Can I get you to email me details and possibly pics of the balanced tuner you sold? Thanks, de Denton WB7TDG

need answers on Feed spreader distance and length

Thu Dec 11, 2014 9:35 am (PST) . Posted by:

w5heh

Would help me to know, best measurement for twin lead spreader, thinking 3 inches for spreader lengths , Distance between spreaders ? 18 " ? , using 12ga, Full wave loop 160meters, thinking around 508 ft but have enough to go longer , distance from loop for Feed twin lead is about 110ft , , want to know best length for Feed , only Twin lead into Heath SA2060A has built in Balun, no Coax will be used . Height will be about 42-46ft , have all ready and two holes dug and filled , just would like any numbers that can be shared with this info.

Appreciate any Chime in on this , THank you , W5HEH 73s, AJ

AJ,

Hard to know since proposed use of antenna is unknown. For example, 160 M monoband or multiband? This will determine the range of impedances that will be encountered which in turn will suggest the spacing of the feeders. It is likely to be non-critical since the loss will be small in most cases. Physical appearance, wind/ice loading, etc. will suggest what type of spacing might offer advantages.

In my loops, 40 M and 80 M horizontal loops, I switched from 450 ohm window line to 300 ohm transmitting twinlead to reduce the visual cross section, for the xyl. Both antennas continue to work well, 40 M as a monobander, and the 80 M loop as a multibander.

Spreaders are readily available from 73CNC, I believe, and they are UV resistant, Lexan (?) black for low visibility and won't break if dropped like glass ones, etc.

73,

Evan, K9SQG

"abe" abemitchell777

In Oregon, on one city lot, I still use an 80 40 meter inverted V fan (it gives me 10-80m). Following is my main antenna for field days and camping, it has went up and down many times at different heights and in different configurations with very similar results. I set my 160 loop up around 1.7MHz (best I remember about 574 ft of insulated 12ga wire). This gives me a pour match for 160m but a good match for the digital part of 10-80m. I remove a section of wire, maybe 50 feet, when I want to focus on 80 meter phone. It is fed with 110ft of 450 ohm ladder line. A 4:1 balun is used on 10 through 40 meter and no balun needed on 80 meter. Little or no tuning is needed for the digital portion of these bands. A good tuner is needed to make 160 usable.
Hope this is useful info,
Abe K7ABE

Us non-city boys go to the local farm supply for ladder line insulators.
http://www.ruralking.com/agriculture/fencing-supplies/electric-fencing/electric-fence-insulators-acce/dare-4-tube-insulator-50-pieces-per-bag-1718.html
50 pc of 4" spacers for the high price of $4.99 , if the link does not work go to Rural King, SKU # 070040553. You can cut them in half and have a 100 PC's for 5 bucks and a few tie-wraps. A tie wrap around the wire and then thru the insulator and your are done. Also dipole ends, 50 cents for porcelain and 25 cents for UV resistant plastic.
There are several name brand supply stores with fence parts and all parts are made for sun proof and good with electricity

Buy some "rozenclips" from amevo

They are use in green-houses to clamp a plant (tomato or roses or) to a wire

Works superb for making ladderline

Sigi, do you have a URL for the AMEVO company.?
The info in the foto does not reference a URL.
Also, SOTA in England has plastic laser cut spacers for open wire line.
I have samples on the way to Ecuador to test.
Thanks for the info

Sigi, they are great clips and you can get then for 3 size wires but the quantity and overseas shipping was a little high for me, good for you. I could not find them over here.

Re: need answers on Feed spreader distance and length

Thu Dec 11, 2014 3:23 pm (PST) . Posted by:

"Ken" wa8jxm

Interesting, I had not thought of using those for feedline spreaders.

What I’ve used is to cut up plastic clothes hangers into 3-1/2” sections (about 7 per hanger) and drill holes near the ends for the wires to go through. It works fine.

Ken WA8JXM

Sigi, the only seller i found here in the USA was this -
But they demand 50.00 minimum order, i did not want to mess with it, 15.60 or so for 100, pack , not bad, i went with the Finned wire fencing 4" tubes , 2.00 per 25, at Tracktor Supply , i can pick with near my Animal Feed store so better for my situation, you can order them online from many suppliers ,one listed in response on this thread . These Secure wire clips look ez to use , some here might want to order a bunch and pack them up so smaller users like myself would buy them .

Sigi thanks again for sharing , just wish these were more ready available here , 73s, AJ W5heh

From: siegfried jackstien
Topic: 4452 Message: 4466

http://www.amevo.nl/plantstokken_boomclips/

i bought a pack of those on a hamfest together with some end isolators
(plasic eggs) ... a ham bought those clips direct from amevo and then he
packed them in smaller packages ... reselling as ladderline insulators

dg9bfc

sigi

ps ... maybe you can make a group buy or also resell them?!?

4468. 2.5:1 Balun

Yahoo group: SkyWires
Date: 2015-01-03 01:05:09 UTC
From: everettsharp@...
Topic: 4468 Message: 4468

Hi All,

I an new to the group and am interested in building either a Sky Loop, or a Delra loop. I would like to feed it with 50 coax and use a 2.5:1 balun. So what I am looking for are plans to construct my own. I have a verity of ferrite core mixes, 61, 52, 43 and 31. I have Jerry Sevick's book on baluns, but did not find a 2.5:1. I did find a UNUN 2.25:1 and have built one. It looks good sweeping it with my MFJ259B, where it is just about flat from 1 to 30 MHz.

Any help,would br greatly appreciated.

Everett N8CNP

You have the right book , look at page 97 and it's reference to moving the tap on 2.25:1 and it is shown on page 67. I made one for a loop myself but later increased the size of the loop so I could use it as a multi-band loop with a 4:1. Now a delta loop.
I am surprised it is flat from 1 to 30 Mhz. What did you use as a dummy load for the test? I also swept mine with a 259B.

From: Everett Sharp
Topic: 4468 Message: 4470

Hi Rich,

I used a 112 ohm carbon resistor. I wound it on a different core than what was called for in Sevick's book and used a FT 140-61 instead. I may have exaggerated the flat part a bit, as it was 1:1 up to about 14 MHz and at 30 MHz it was 1.2:1, which is still not bad.

I want to be able to operate multi-band also, did you find the 4:1 better than the 2.5:1 for multi-band? Also is your 4:1 a current type, with two 1:1 toroids wired in series/ parallel. That is what I am using on my Windom.

4471. Re: [SkyWires] 2.5:1 Balun

Yahoo group: SkyWires
Date: 2015-01-03 03:02:16 UTC
From: Evan Rolek
Topic: 4468 Message: 4471

For multiband use, I've never been happy with a balun of any ratio for my horizontal loops. Whatever the ratio, it is right on for some bands, too low for others, and yet too high for some. Using open wire line or window line, with a tuner in the shack, solved a lot of problems for me, not the least of which can be core saturation for the balun. I'm not anti-baluns but I've been happy with the simplicity of my installation that has worked well for me. You mileage might vary...

Evan,

My plan is to build a loop for 40 meters, cut to 7.1 MHz, which should work out for 14.2, 21.3 and 28.4 MHz. I do not want use open wire feed as it is too difficult to get to the shack. So a balun is my only option. I will only be operating 100 watts, so it should not cause any overheating problems with balun and based on my experiments, I will more than likely use 61 material, which has a perm of 125.

4473. Re: [SkyWires] 2.5:1 Balun

Yahoo group: SkyWires
Date: 2015-01-03 03:38:19 UTC
From: Evan Rolek
Topic: 4468 Message: 4473

Everette,

I realize everybody has different constraints. I've been using window line, now 300 ohm transmitting style instead of the 450 ohm I used to use, and find that it works quite well for me even though I violate all the rules for its use. I have several 90 deg bends, some quite abrupt, run the line indoors through the basement where it runs close to water pipes and heating ducts, and so forth. Being able to tune things in the comfort in the shack is a real benefit to me. From my measurements in the shack, the line is almost perfectly balanced in spite of the rules violations. If there is a downside to my installation, I haven't found it yet, hi hi. But I can appreciate the fact that some installations might be impossible or extremely difficult.

Please keep the group informed of your progress.

73,

Evan

Subject: Re: [SkyWires] 2.5:1 Balun

Hi Rich,

I used a 112 ohm carbon resistor. I wound it on a different core than what was called for in Sevick's book and used a FT 140-61 instead. I may have exaggerated the flat part a bit, as it was 1:1 up to about 14 MHz and at 30 MHz it was 1.2:1, which is still not bad.

I want to be able to operate multi-band also, did you find the 4:1 better than the 2.5:1 for multi-band? Also is your 4:1 a current type, with two 1:1 toroids wired in series/ parallel. That is what I am using on my Windom.

You have the right book , look at page 97 and it's reference to moving the tap on 2.25:1 and it is shown on page 67. I made one for a loop myself but later increased the size of the loop so I could use it as a multi-band loop with a 4:1. Now a delta loop.

I am surprised it is flat from 1 to 30 Mhz. What did you use as a dummy load for the test? I also swept mine with a 259B.

Everett, great reading on you set up.
My loop is a little smaller than I would like, it is a 160 size, 2X160 would be better but a lot of trees in the way. I put it up then adjusted for best SWR to the lower part of the 40M band.
My first balun build was a duel wind Guanella on a on a large single core, 2nd was with two torrid cores. The one I am using is two rods in a series/parallel like you mention.
I dont have a print out of my 160 size antenna but here are the final readings on a 80M size delta a multiband set to the 20M band. All is not perfect for all bands but workable with my internal tuner. So it can be used on more than one band.

http://i1102.photobucket.com/albums/g453/KD0ZZ/80MLoop_zpsa6e4cfe7.jpeg

As of today I use a 160 size loop on 160 thru 40, a Hex Beam on 20 thru 6, and a 30M vertical, tomorrow ?????

Rich,

I took a look at your pictures and I can see that you like to build and experiment like I do. I noticed that some of your balun experiments were with iron core toroids, you might want to try ferrite. I like the 61 mix and 43 mix for most of the baluns that I have experimented with. On your 4:1, using rods, I noticed that you gave the diameter in mm, are they some of the Russian ones off ebay?

The SWR that you show on the chart for the 80 meter loop looked quite good, I would be happy with those numbers.

I did some more digging this morning on the web and found that Balun Designs make a 2.5:1 balun and they also have in the box a 1:1 balun which is between the 2.5:1 and the antenna. Baluns Designs claim to have custom mix toroids, I don't know if that is true, or not. They also give some recommendations for wire lengths for 40 and 80 meter loops, using their balun.

About the rods, yes and no. Yes the first rods were from a Lithuanian ham selling Russian military surplus on E-Bay size10MM x 200MM,
I also have some .5" x 8" flea market specials given to me by the kindness of K5EST. They were un-used in a shipping container but no markings. I notch them with a diamond saw for a clean snap off point.

http://i1102.photobucket.com/albums/g453/KD0ZZ/160%20Loop/TrimRod_zpsa847fe7a.jpg

In the above album you can see the trees I had to cut to make it a 160 loop. I would like to double the size to make it a better match on 160 but it is hard on my old fused back at 70.
Also my first windings were mag wire with monofiliament spacing as in W2FMI book. I later changed to speaker wire for built in spacing and use a dab of epoxy to hold in place plus the two toned color makes it easy to identify.
I did try one or two with Teflon covered wire but very springy and hard to hold in place. I don't run a lot of power so not really needed.
Check out Mega Loop by M0MCX, this is where I got started with the loop and balun and a 200 ohm antenna.

4477. RE 4:1 Balun in Tuners like mine

Yahoo group: SkyWires
Date: 2015-01-03 22:17:57 UTC
From: email4utoo@...
Topic: 4477 Message: 4477

We probably have gone over this , but humor me, i am about to finally lay out and raise over 550ft of wire on four EMT conduit masts up 36-42 ', this is just for backround info, 12 ga solid wire , already to go . made my own 150ft +- Ladder line 2-3.5 inch spread to Shack's Tuner , ok, now have a 2060A Hkit Tuner as a big Balun inside , now will be running 100 watts , but on the drawing board and collecting parts and boards for Solid State amp 900-1200 watts , will be backing it off to about 800 most of the time to conserve all and believe not needed most of the time .
Ok so your 3 cents on considering disconnecting Balun when i fired up amp eventually ??
Will use my Rig mostly on 40m, but will move to other bands for Nets and Fun , not a real DX chaser but i call them if i hear well. Nets and learning from others is where my interest lies ,but my ts930 will cover 160-10 m .

Thanks for all info , AJ W5HEH

Topic: 4468 Message: 4478

Hi Rich,

I am no young guy either, having just turned 72. I find it more difficult to do somethings, but I will try anyway. Here is the link to Balun Designs 2.25:1 balun, where he has sweep data on his balun and info on two different Sky Loops.
http://www.balundesigns.com/model-25112-2-5-1-balun-1-5-54-mhz-2kw/

My question is do you really need the 1:1 balun between the loop and the 2.5:1 balun?

In doing some research on the web there was a Cubical Quad antenna called "Lighting Bolt", it used a 2.25:1 UNUN balun, which from reviews was reported to be a very good performer. It was rated for 1 KW and used a very small ferrite core, FT140, or FT150. As I mentioned I wound a 2.25:1 on a FT140-61 core and it looked very on the sweep. I will take a look at it by adding a 1:1, using a bifilar winding on it, which would typically be 100 ohms, Balun Designs says theirs is 125 ohm, so it may take a little more spacing between the wires on the bifilar winding to get 125 ohms.

I would like to get my loop up while the leaves are off the trees in my yard. Here in Alabama, that give me till early April.

4479. Re: [SkyWires] 2.5:1 Balun

Yahoo group: SkyWires
Date: 2015-01-04 14:45:54 UTC
From: Rich Schmuke
Topic: 4468 Message: 4479

Well I have never been a fan of needing a separate 1:1 before the transformer. I do have a "ugly choke" just under my 4:1.
Does it help??? Don't know but it is there.
I have always been under the impression that a basic loop was around a 100 Ohm antenna, of course depending on height and surroundings. A larger loop of multi wave lengths become closer to a 200 Ohm antenna thus a 4:1 seems to work well for me. The only time I used 160 was on the ARRL/portable contest so my 160 size loop is used for primarily 80 & 40 , now and then on 20 if I don't want to rotate my beam. I had a full size 40M vertical with a raised feed point about 8' off the ground. with nice drooping radials. My loop most always out performed the vertical by several "S" units so my 40 is now a 30.

Rich, KdØzz

4480. Re: [SkyWires] 2.5:1 Balun

Yahoo group: SkyWires
Date: 2015-01-04 16:48:53 UTC
From: Everett Sharp
Topic: 4468 Message: 4480

The Balun Designs 2.5:1 balun has the 1:1 between the antenna and the 2.5:1, not after. It is good to use 1:1, just after your 4:1, or what ever balun, as it reduces, or eliminates the common mode currents. I am currently running a 80 through 6 Meter Windom, which uses a 4:1 and I have a 1:1, 10 turns of RG8X wound on a FT240-31 core and the 2 more 1:1 baluns after that in the line to the shack.

> I have always been under the impression that a basic loop was around a 100 Ohm antenna, of course depending on height and surroundings. A larger loop of multi wave lengths become closer to a 200 Ohm antenna thus a 4:1 seems to work well for me. The only time I used 160 was on the ARRL/portable contest so my 160 size loop is used for primarily 80 & 40 , now and then on 20 if I don't want to rotate my beam. I had a full size 40M vertical with a raised feed point about 8' off the ground. with nice drooping radials. My loop most always out performed the vertical by several "S" units so my 40 is now a 30.

4481. 28th Annual NASWA Winter SWL Festival

Yahoo group: SkyWires
Date: 2015-01-16 21:12:06 UTC
From: ve2shw@...
Topic: 4481 Message: 4481

THE 28th ANNUAL NASWA Winter SWL Festival, Plymouth Meeting, Pennsylvania- February 27 & 28, 2015
The largest annual gathering of radio enthusiasts in north-eastern North America, bringing together shortwave listeners, DXers, AM/FM/TV DXers, scanner enthusiasts, radio broadcasters, Internet broadcasters, amateur radio operators, and others. Exhibits, workshops and lectures on all aspects of radio. 2 days of nothing but radio. If you love radio, you should be here! February 27 and 28, 2015. See www.swlfest.com http://l.facebook.com/l.php?u=http%3A%2F%2Fwww.swlfest.com%2F&h=cAQHgrdHS&enc=AZPt8HmjfsxwJyjTVUqIKyLQCwrmOTKtsiVez8qOI0a4s2v02ekttqv88l0ghGU5z1yHnVXQwTfjUOVGJA9_ji2_wTp47b2eDq4Rb2ddvwPyPPWRhanrfYnDHkZhuliCCX6pO3q3Rx50wjW3YGlZNQJs&s=1 for full details

Hello Jay
I have a 1000 ft + loop as well and have my inverted L with elevated radials inside the perimeter of the loop! I haven't noticed any negative interactions to date! (Both antennas have been up for over a year now.) I am however looking into de-tuning the inverted -l for noise reasons…i.e. re-radiation of vertically polarized local noise?

A faster approach is to tune up using either of the respective antennas. Then, ground the unused antenna and see if it "significantly" affects the other antenna. Then do this for the other antenna. Yes, coarse at best. Sure a lot faster than using analysis software by an order of magnitude.

Yes, indeed. What I have experienced is that every antenna is a compromise. Factors include "performance", size, cost, site specifics, requirements/goals, etc. etc. Using analysis software is great for a yet to be installed antenna, and after that phase, it is a matter of dealing with constraints, site specifics, etc. etc. Sure is more fun than veging out in front of the TV!

From: Thomas F. Giella W4HM
Topic: 4482 Message: 4488

I have a 300 foot long horizontal loop in a square with each leg 75 feet long. It's up at only 35 feet at each of the four corners and is fed with 41 feet of 300 ohm window line to an MFJ-974HB balanced antenna tuner.

Inside it I have a 129 foot long inverted L with a 60 foot vertical section. I see no appreciable interaction between the two when I do the grounding thing.

Inside it I also have a 60 foot tall wire vertical for 80 meters. I do see some interaction between the two 80 meter antennas when I do the grounding thing and the 60 foot vertical does impart some noise into the 300 foot long horizontal loop.

All three antennas work very well on DX.

Thanks for your empirical observations Thomas! I for one always enjoy hearing about how a "practical installation" works in comparison with the "computer models". And like they say, the best antenna design on paper doesn't work as well as an installed antenna, hi hi. Similar to your experiences, I noticed no interaction between my GAP Challenger vertical and my 40 meter horizontal loop; vertical was "inside" the area encompassed by the loop, and the antennas were maybe 10 ft apart.

73,

Evan

Computer models are just that - models. While "practical installations" trump counting atoms with silly models of dubious merit, it can save a great deal of time and effort. But that is just stupid egg-head science stuff - probably with some worthless liberal agenda

A tennis ball launcher will put you on that list???

In some states in the us you can run around with a gun ... and a tennis ball launcher (with compressed air and no explosives) is counted as a teroorists weapon??? ... wow ... how complicated weapons law can be :-)

www.antennalaunchers.com

that is where I get the idea from

but ... I added such a sprinkler valve plus barrel to a garden sprayer

and so I have the tank with pressure gauge and pump included

easy to work with (and not as dangerous as using a bow and arrow or fishing weight plus sling-shot)

Slightly weighted tennis ball comes out with only 30-50 miles (roughly half the speed of a tennis serve) and so it is not dangerous even if you hit somebody with that ball

It is a matter of interpretation with regard to local laws. Some of the "antenna launchers" fit within the definition of "zip gun" so it is hard to know what the results might be.

One thing that simple empirical testing can not, is distortions to pattern. You may not see any interactions with the SWR, but the pattern could be distorted or enhanced.

Absolutely. That is why the empirical test is a coarse estimate.

One thing that simple empirical testing cannot, is distortions to pattern. You may not see any interactions with the SWR,but the pattern could be distorted or enhanced.

It is a matter ofinterpretation with regard to local laws. Some of the "antennalaunchers" fit within the definition of "zip gun" so it is hardto know what the results might be.

A tennis ball launcher will put you on that list???

In some states in the us you can run around with a gun ... and a tennis ball launcher (with compressed air and no explosives) is counted as a teroorists weapon??? ... wow ... how complicated weapons law can be :-)

www.antennalaunchers.com

that is where I get the idea from

but ... I added such a sprinkler valve plus barrel to a garden sprayer

and so I have the tank with pressure gauge and pump included

easy to work with (and not as dangerous as using a bow and arrow or fishing weight plus sling-shot)

Slightly weighted tennis ball comes out with only 30-50 miles (roughly half the speed of a tennis serve) and so it is not dangerous even if you hit somebody with that ball

......

4498. Question about ground a loop antenna

Yahoo group: SkyWires
Date: 2015-01-26 18:49:10 UTC
From: joel1847@...
Topic: 4498 Message: 4498

I've got a 1550'-ish size loop, not quite a rectangle cause I had to go around some buildings and tried to get away from some power lines. The loop is run through the olive trees and averages about 10 feet off the ground. Wire is 10 and 12 gauge THHN and insulated from the trees using electric fence insulators. Feedline is a crazy idea I had using 12-2 Romex as a parallel feeder and I made two chokes at either end of the feeder using the black and white wires wrapped around an 8 inch bolt and then wrapped the whole thing in electrical tape to keep the wires intact. Kinda of a hairbrained idea, but it does work well.

My question is, has anyone used a separate ground wire under the loop to minimize ground losses and then just feed the loop as an end fed? I've got a big roll of aluminum electrical fence wire that I could string along under the loop if it would make a difference.

The main reason I went with a loop was because I've got two 12.5kva high voltage lines on two side of the property and during the dry months, the noise is absolutely horrid.

Thanks

Joel,

As a user of horizontal loops, and having done some research, I'm not an expert but I'll afford some observations/experiences.

The effect of a ground wire under the loop depends on the ground conductivity in the area. If it is good, you might see minimal to no effect. If the conductivity is poor, then you might see an improvement but, if you do, it depends on the frequency you are operating on and the percentage of wavelength spacing between the loop and the ground wire.

My guess is that you have some feedline loss there. The Romex has spacing that is less than 300 ohm transmitting twinlead and so you have some degree of mismatch depending on what bands you operate. Feedline chokes are typically used with coax, not parallel feedlines and I suspect the chokes at either end are quite lossy and may be upsetting the balance of the feedline conductors.

I'm sure some experts can offer their guidance which will be more informed than what I can provide.

Looks like Yahoo ate my other response so here's another.

I originally fed this loop with a long chunk of RG-6, which at HF should have been fairly low loss at QRP levels. When I tried the Romex, there was a significant increase in signals heard, so I assumed it was a lower loss. I messed up though and didn't test before and after using the chokes, so I can't say anything about the usefullness of them without cutting them out of the system. I've got some other testing I'd like to do before I do that though. I went with Romex as I was trying to go for low loss and was trying to match the impedance of the loop as best I could without using a lossy balun. I read somewhere that the lower to the ground the loop is the lower the impedance, but you end up with more ground losses which is why I was hoping to limit that somehow.

4501. Antenna interactions

Yahoo group: SkyWires
Date: 2015-01-27 15:08:58 UTC
From: Evan Rolek
Topic: 4498 Message: 4501

Forgot to mention an observation which I believe is common knowledge. However, sometimes we need refreshing, I know I do, hi hi.

I have two antennas currently, basically a 40 m and 80 m horizontal loop. Even if the unused antenna is on a non-resonant band/frequency, it still picks up RF energy; it is, after all an antenna. An issue arises when the feedline of the unused antenna comes into the shack. It will be bringing RF into the station and going to an antenna tuner, possibly to a balun (which has a terminal connected to "ground"), or left hanging by being unterminated. Depending on station specifics, this may or may not cause problems like RF on transmitted audio, causing meter deflection on the tuner for the unused antenna, etc. Hence, whether the unused antenna affects the radiation pattern of the antenna in use, there is still the possible issue with RF in the shack. How it manifests itself depends on site specifics.
I've had my share of experiences with the above issue but not sure how widespread it is. At any rate, I enjoy using my horizontal loop antennas.

From: Andy
Topic: 4498 Message: 4502

If I read correctly, you are asking about using your loop as a monopole, or as a top hat capacitive load on a vertical wire in the vicinity of the loop.

Those who love loops might wonder why you would do that. Surely your loop is big enough to cover even 160 meters. And I think you would lose the balanced loop's ability to reject QRM from the power lines (though that ability might be compromised with it being so close to the HV lines). Feeding the loop against the reflector wire on the ground, makes your antenna unbalanced, and more susceptible to some kinds of noise.

From what I have seen on the 'net, there doesn't seem to be nearly as much experience from people using a "ground" or reflector wire under a loop, as there is people asking or talking about trying it. People doing NVIS talk about trying it, but that would be using the loop as a loop, not as an end-fed monopole.

Romex might have somewhat higher loss than an open wire feedline because more of the environment around the wires is filled with plastic. The beauty of open wire feedline is that the dielectric around it is 95-100% low-loss air. Coax replaces much of that air with plastic, which is why it has more loss. But other than that, Romex might not be such a bad idea. You may have seen the criticism about using zip cord as feedline; it seems it makes a good antenna but might be a poor feedline.

I don't see your choke baluns being a problem either. They are transmission line transformers and the bolt used as the core is energized only by common-mode signals, so if the core gets lossy to those signals, that should be seen as a good thing. The normal differential-mode signal shouldn't "see" the bolt.

Andy

4504. Re: [SkyWires] Question about ground a loop antenna

From: Evan Rolek
Topic: 4498 Message: 4504

It seems that iron/steel are used as cores for transformers in the 60 hz region. However, none of the commercial manufacturers that I know of use iron, only ferrite. Is there some hidden advantage to using a steel bolt as a balun core? Inquiring minds want to know...

From: joel1847@...
Topic: 4498 Message: 4505

No hidden reason that I know of. It was just an experiment with what I had on hand really. I try to use what I have on hand or can get locally so that I can obtain spare parts easily. I really don't like to have to rely on mail order stuff to build or complete projects and I like to have redundant backups. 5 years 10 months of Navy training really hammered that home. The homebrew "baluns" or chokes might be lossy or they might not. I should have tested them before installing them so I would know for sure. Unfortunately it's part of the feedline so doing it after the fact might not be possible without cutting the line. I was thinking that I wanted to keep out any common mode currents and possibly keep out as much powerline noise as possible. And the bolt had these nice threads that helped me to keep the wires spaced just right. A larger diameter bolt with different pitch might be better to keep the impedance more uniform with the close spacing of the Romex. Part of the low lossness (is that a word?) of ladderline has to do with the diameter of the conductors, so I figured with a 12 or 10 gauge Romex, it should be close to ladderline losses. Plus it was free and I wouldn't want to use it for electrical as the outer jacket had some cracks in it which didn't really matter to me if I used it for a feedline as long as the two inner conductor jackets were okay. I need to do some testing, but so far it works smoking hot on 30 and 20. I should probably put up a reference antenna to compare it to (again). It's way better than the G5RV and the 40-10 vertical I had up, although the vertical was better than the G5RV. It's been fun and the only cost I have in this huge loop is the fence insulators. Everything else was free.

4506. Wire supports

Yahoo group: SkyWires
Date: 2015-02-01 19:02:34 UTC
From: D. Scott MacKenzie
Topic: 4506 Message: 4506

Looking at putting up a loop again. Tried putting in trees, but keeps coming down. Looking over my small yard, I came to the conclusion that my fence is just the right size for a loop, with a nearly square circumference of 260 feet. So, putting up a loop at each of the four corners would work nicely. What I was looking at doing, was making some supports about 25-35 feet tall using PVC pipe. If I pick the sizes carefully for proper nesting, I can split the ends and use muffler clamps to hold them together. I can paint them a forest green or similar to hide them although there is no reason to do so as my community encourages ham radio. Even on my small lot I can put up to a 90' tower with out permits.

Any downside to using PVC as a support?

Scott

Will get brittle ... why not use fibre glass tent poles?!? (milgrade ... used for camouflage nets .... already in dark green hi hi)

I would not use pvc tubing for 35 feet height

You can use that for maybe 25 feet but the tubes will break after a short time

And you have to use some guy wires/ropes ... your loop will pull the poles (regardless if pvc or fibre glass) innerwards ... so some guying is needed anyway

Good luck :-)

Scott,

My experience is that PVC pipe bends over time due to UV exposure and/or sustained pressure/pulling. Have had much better luck with fiberglass masts that I have been using for almost 20 years.

I agree that fiberglass is a much better solution. The advantage is that PVC is cheap, and I can make each support for about $10-15. Since only going up about 25-35 feet, easy to replace and nothing lost if it doesnt work. If I am satisfied with the antenna performance I can then look at upgrading the supports.

I tried a PVC support and found two sections that would nest together. I inserted the smaller one into the larger with the slight natural curve in opposite direction so it would be as straight as possible. Glued the parts together but it only took a few months for it to bend in the wind just holding up a J-Pole. The PVC will last no time with a side load from a loop, IMHO.
Here is a sketch of the support I use for 20 to 30 ft needs.
http://i1102.photobucket.com/albums/g453/KD0ZZ/Tilt2.jpg
A larger and simpler to make one for 40 to 50ft needs can be found in album. I use it for the feed support for my 160M size delta loop.
http://i1102.photobucket.com/albums/g453/KD0ZZ/TiltOverB-1.jpg
The other two points are in trees with a counter balance on pulleys .

Here in dl you can get the used camouflage net poles for around 3 dollar each (military surplus)... makes25-30 bucks for your needed height (and will last forever)

Here is what I used, their light gray color blends right into the sky and back ground, no painting needed, just unscrew the brass ball off the top. plus it already has connectors for the flags that I used for hanging my wire. and real easy to raise and lower if wire repair or changes need an being aluminum it last of ever !

Good luck ! http://www.harborfreight.com/20-ft-telescoping-flag-pole-kit-95600.html

4514. Alpha Delta DX-B for 160, 80, 40, 30m

Yahoo group: SkyWires
Date: 2015-02-05 22:10:15 UTC
From: pa0tbr@...
Topic: 4514 Message: 4514

Hi,
I want to expand my activity to 160, 80, 40, and 30m but have not much space to put up much of an antenna for these bands. I laid my eyes on the Alpha Delta DX-B which matches the space I have available.
I have a pole with Hex beam on my concrete roof and could mount the DX-B about 4m above the roof. I am interested in working DX, not local rag chew.

Before I order I like to hear of any experience, good or bad, with this antenna.

I know that bigger and higher is better but I don't have space for bigger and legislation restricts the height.

73,
Ton PA0TBR

It will work for these bands ... but on the lower bands it sure will be a cloudburner (not very good for dx)

Youre welcome :-)

For dx on the low bands you need a vertical (a low hanging dipole is a cloudburner)

What about an inverted l antenna?!? .. what you need is a low radiation angle ... and that does not work with a dipole close to ground (and for 160 any height is close to ground cause you can not lift the dipole up to 80m height)

So ... faor ragchewing to the next states your dipole will work fine ... for dx not cause it is just hanging tooo low over ground

From: email4utoo@...
Topic: 4519 Message: 4519

Ok, Just built 160 meter Full Loop, 550ft square , fed with homemade ladder line with 3 " spreaders - about 150ft long feed , no Coax, into oldie but goodie, Heathkit 2060A Tuner .

Four Poles up about 38ft - are those EMT conduit pipes from 2 1/4 " down to 3/4 inch , so 5 total x 10ft sections , slid together about 22", can be bolted or MIG weld nuts with set screw as i did , then short PVC shoved and grounded to fit and screw in, , with T to run Paracord or rope to pulley then to insulator to hold wire ,these Poles are flexable and bend some , so do not let it worry yahs, used a clete like on boat masts to tie each individual line , (you can use these lines as a guy, as i did on a couple) ,, used 12 GA , but i would use 14 ga next time, due to snap spreaders available for 14GA wire , easier and faster to make your own ladder line .

Working fine so far on 160 ,80, 40, 20 meters ,with SWRs 1.1- 1.25 , a friend is coming over with Antenna Analyzer to check it all out .
I do notice it loads much easier when wet from rain , so any suggestions would be helpful .
Getting Great Reports , and it is quiet and has very good ears .

With all that said, i am studying other Wire Antennas, like a Double Horizontal Delta Loop one over another feed the top and reflect from the bottom , one will fit inside the other , This Operator had a very strong signal .
The other is a Wire Beam , and Joe Carr's Diamond with ladderline goes thru the center . I have not used Antenna Software would be fun to use once mastered .

Hope this helps someone considering a long Loop, simple brief , any questions , i am good on QRZ d . 73s, AJ W5HEH

Can you lay down a few dozens of radials?!?

The inverted l (and all other antennas that are fed against ground) needs a GOOD radialfield below it to work good (otherwise you are cooking the worms in your garden)

Greetz

Sigi

Ps good luck with any antenna project :-)

4531. Just Installed a loop

Yahoo group: SkyWires
Date: 2015-03-22 15:45:45 UTC
From: everettsharp@...
Topic: 4531 Message: 4531

Yesterday, 3/21/15, I installed a 80 Meter Horizontal Loop that is 264' long, average height of 30', roughly in a rectangle of 50' X 82', with the feed point in one corner, using a Balun Design's, Model 25112 - 2.5:1 Balun 1.5 - 54 MHz - 2kW.
The Balun Design's website recommends using 247' to 251', height dependent. However, this is for a triangle, Delta configuration, but as can be seen from the above I had to use 264' for my rectangle configuration. I used a Rigexpert AA-170 antenna analyzer to help with the tuning process. The antenna works on all bands with the exception of 30 meters. The only disappointing result was how narrow the band width is on 80 meters, with a 3:1 SWR window of 3.5 to 3.876 MHz. The lowest SWR was on the 80 meter band, which was 1.12:1 on 3.678 MHz. One of the very noticeable things about the antenna, is how quite it is over the Windom antenna that I was using. Also I now have a lot more bands available to me with this antenna, than I had with the windom.

Band Bandwidth window@ 2:1 Bandwidth window@ 3:1 Lowest SWR
80M 3.579-3810 3.5-3.876 3.678 1.12:1
40M 7.176-7.44 6.978-7638 7.341 1.83:1
20M 14,463-14.667 13.941-15.063 14.535 1.93:1
17M 17.934-18.165 17.472-18.627 18.0 1.97:1
15M 21.366-21.828 20.937-22.290 21.597 1.69:1
10M 28.527-28.932 27.5-30.045 28.725 1.88:1

From: Don Sanders
Topic: 4531 Message: 4532

The loop seems to be working very well. The bandwidth 80 is about normal
and almost 2 X what a dipole will allow. 80 meters is a broad band as
percentages of frequency goes and is the hardest to have full band coverage
without a tuner.
As with most multiband antennas you will probably need a matchbox for
working higher on 80 and for 30 meters. One thing you can do is install a
30 meter inverted vee at the feed point or separately with its own coax
feedline..
Don't fret too much, enjoy your new skyloop.

Don,

Thanks for the reply and comments. I may trim a little more off of the length after I use it for awhile. Also I have constructed a 2.25:1 balun, copy of the Sevick design, on a F150-K core and will try it on the loop to see if will work as well. I think that the Balun Design's balun uses the same F150 core, wound in the same 2.25:1 configuration, but has a 10 turn bifilar winding on a FT240K core, between the antenna and the 2.25:1 balun.

From: Evan Rolek
Topic: 4531 Message: 4534

From my experiments with horizontal loops for the past 20+ years on 75 and 40 meters, I've not seen any performance differences between a loop that is operated on a resonant frequency as opposed to one that is "off frequency". I just adjust the antenna tuner for a match and go with it.

In the past, I used 450 ohm window line but a couple of years ago I switched to 300 ohm transmitting twinlead. It was a better "match" to the impedances of the two loops I have, for the bands that I operate. From my measurements and analysis, there was no single ratio of balun that would be what I consider to be an acceptable solution to my operations on all bands of interest; in addition there might be some extra loss from the coax had I opted to go with that approach. With the transmitting twinlead, and the tuner in the shack, I'm very pleased with both the 40 meter horizontal loop (at 12 ft above ground) and my 80 m loop at about 20 ft above ground.

On 160 meters, I bring the feedline from the 80 m loop straight down, tie the conductors together, and feed it against ground. This is described in many ARRL publications but I've never found anybody that has used it other than myself. Obviously, it is not popular but I'm very pleased with the configuration.

As a side note, I use some weatherproof quick disconnects so I can get the feedlines away from the house when storms approach.

Let's all enjoy the hobby. If your wish, I hope you have a safe, enjoyable visit to Dayton for Hamvention 2015.

73,

Evan, K9SQG

The loop seems to be working very well. The bandwidth 80 is about normal and almost 2 X what a dipole will allow. 80 meters is a broad band as percentages of frequency goes and is the hardest to have full band coverage without a tuner.
As with most multiband antennas you will probably need a matchbox for working higher on 80 and for 30 meters. One thing you can do is install a 30 meter inverted vee at the feed point or separately with its own coax feedline..

Don't fret too much, enjoy your new skyloop.

From: D. Scott MacKenzie
Topic: 4531 Message: 4535

I agree - I have had much better luck with ladder line than with using baluns. Will be putting another loop up this Spring (Will it ever arrive?) and have it in the air about 25 feet or so. Mostly I will use it for Field Day and Sweepstakes and that is about it - only turn on the rig about once or twice a year anymore...

Subject: Re: [SkyWires] Just Installed a loop

From my experiments with horizontal loops for the past 20+ years on 75 and 40 meters, I've not seen any performance differences between a loop that is operated on a resonant frequency as opposed to one that is "off frequency". I just adjust the antenna tuner for a match and go with it.

In the past, I used 450 ohm window line but a couple of years ago I switched to 300 ohm transmitting twinlead. It was a better "match" to the impedances of the two loops I have, for the bands that I operate. From my measurements and analysis, there was no single ratio of balun that would be what I consider to be an acceptable solution to my operations on all bands of interest; in addition there might be some extra loss from the coax had I opted to go with that approach. With the transmitting twinlead, and the tuner in the shack, I'm very pleased with both the 40 meter horizontal loop (at 12 ft above ground) and my 80 m loop at about 20 ft above ground.

On 160 meters, I bring the feedline from the 80 m loop straight down, tie the conductors together, and feed it against ground. This is described in many ARRL publications but I've never found anybody that has used it other than myself. Obviously, it is not popular but I'm very pleased with the configuration.

As a side note, I use some weatherproof quick disconnects so I can get the feedlines away from the house when storms approach.

Let's all enjoy the hobby. If your wish, I hope you have a safe, enjoyable visit to Dayton for Hamvention 2015.

73,

Evan, K9SQG

Everett, from the info you put on the files section of the group, it appears your loop is too short.
The frequencies of lowest SWR are too high. If you take the standard formula for loops, 1005 divided by frequency, then 1005 divided by 3.6 MHz is 279-280 feet. While this formula is a "ballpark" it is not accurate. In reality the size of the wire, location, height above ground, and more all affect the length. So you may need more wire not less.
Many builders have found 1020 to 1040 divided by freq is a better length for their location and installation.

Often the published / recommended lengths are for the phone bands not CW or multi-mode operations, For instance, 1005 divided by 3.9 MHz is 257 feet, closer to your 264 feet. Short length will cause all bands above the fundamental to show lowest SWR at much higher than even integer multiples due lack of end effect.

Loops should be fed with baluns with two cores, one at 4 to 1 or 6 to 1 and a second with a 1 to 1 balun connected to the feed line. This will not only do the impedance matching but also reduce the currents on the outside of the coax. Careful with Sevick's designs as many were UN-UN designs not balanced to un-balanced. Also he did not use separate cores.

My loop is 274 feet but I feed with parallel feed line, a 1 to 1 balun and short coax to matchbox. So my length is not so critical as would be with coax feed line. Actually I just added wire connecting the ends of my 80 meter Inverted Vee and raised the whole antenna as high as possible above ground. Mine is at top of 12 meter bamboo poles.

Don,

The Balun Designs 2.5:1 does use a UN-UN 2.25:1 balun in the box along with a 1:1, with bifilar turns between the antenna and the UN-UN balun.

I also thought that the length was short based on the calculations, however, here is what I got in real life:
282' 3.54 MHz, 275' 3.62 MHz, 268' 3.67 MHz and 264' 3.678 MHz. So the question is why do I have the 3.67 MHz resonant frequency at that wire length, with the calculated wire length of 273' and if you take into account the velocity factor for the insulation on the wire, which would be 95%, than you would end up with a length of 259.5', which is shorter.

Now if I use the 1020 divided by 3.678 = 277' X .95 = 263.5', which is very close to the length that I arrived at through trial and error. I have a two core 4:1 current balun that I built and I will try it and will run the same scan on with my antenna tantalizer. Also as I mentioned before I also have a 2.5:1 UN-UN balun that I built that I will try too. I have a MFJ -854 and will check the current on the outside of the coax with each balun.

I know that open wire is the best way to feed a loop antenna, however, there is no way to get it into my shack. I have read where some use ladder line to a 4:1 balun and then coax into the shack, but the length of coax must be very short. I can't do that either, as the coax run through my house to the shack is about 55 to 60'.

Once I have evaluated all of the baluns, I will post the results.

Everett:

My 80 meter vertical loop is about 40' off the ground and resonate at about 3.1 MHz. I Feed it with about 200' of 450 ohm ladder line, a 4:1 10kw balum and about 3' of coax into a MFJ 1.5 kw auto turner. Even with the less than ideal tuner, it tunes all bands. It is set up so that one of the clover leaf patterns should be pointed at Europe on 40.

Works well, although I would not run 1.5kw on 160 into it.

Not too worried about resonate frequency, I use it as a non-resonant antenna. If it is tunable, use it! Low on some bands, high on others -- still within the range of the tuner. Also, the tuner in my rig tunes it okay.

4539. Re: [SkyWires] Just Installed a loop

Yahoo group: SkyWires

From: Don Sanders
Topic: 4531 Message: 4539

Yes, as I stated the formulas are ballpark and every real installation is unique.
The reason I said it was short was not the freq of low SWR but the fact that the lowest SWR on all the higher bands are way above the ham bands. This says the antenna may be too short. If the SWR on 80 was at 3.550, the other bands would be lower SWR closer to the ham band.
However when I used coax to the loop I adjusted so all the SWRs were under 3 to 1 at the band center, except 80 as I only operate 3.5 to 3.8. Then the tuner would take care of the final tuning.
Yes the long coax run would be difficult for 450 line. Though the losses on the higher frequencies will be noticed with coax. Maybe a remote tuner where the coax enters the house and 450 line to the antenna from there. That may make as much as 6 db improvement on some bands. The coax loss would be minimal and more RF would reach the antenna.

4540. Re: [SkyWires] Just Installed a loop

Yahoo group: SkyWires
Date: 2015-03-22 21:00:20 UTC
From: Jhallender
Topic: 4531 Message: 4540

I have had good luck w 295 ft of wire fed with 450 ohm ladder line into elekraft t1 tuner. Loop is strung around back yard about 10 to 20 ft high. With k2 xcvr I am mostly a cw op on 40, 30, 20, 15 m with 10 to 12 w. Antenna also will tuneup fine all across 75-80 m band. I open a sliding window to shack and fill the opening with a narrow wood strip that fits snugly into window frame with weather stripping on either side. I cut a narrow slot for the ladder line to pass through and stuff some steel wool into the slot to make it airtight. Quick and easy.

4541. Re: [SkyWires] Just Installed a loop

Yahoo group: SkyWires
Date: 2015-03-23 07:18:29 UTC
From: Tom Hatton
Topic: 4531 Message: 4541

Hi Don,I have been using a 283 meter loop fed with 300ohm ribbon all the way to my MFJ 989c Coupler for the last 10-12 years with out any Balun or choke in the system at all.? And the loop will tune from 80m -10m with no problems You only have to watch out for any METAL very near to the feeder just make sure it dose not touch the metal. I replace the feeder every couple on years or so. With 400w, I also use the loop as a top loaded Vertical on 160m as well, Just connect the two feeder wires together and feed it as a single wire thru the Coupler, A 20m vertical with a 80m top hat Capacitor Too easy..
Tom VK4ATH -.-

Subject: Re: [SkyWires] Just Installed a loop

Don, The Balun Designs 2.5:1 does use a UN-UN 2.25:1 balun in the box along with a 1:1, with bifilar turns between the antenna and the UN-UN balun. I also thought that the length was short based on the calculations, however, here is what I got in real life:282' 3.54 MHz, 275' 3.62 MHz, 268' 3.67 MHz and 264' 3.678 MHz. So the question is why do I have the 3.67 MHz resonant frequency at that wire length, with the calculated wire length of 273' and if you take into account the velocity factor for the insulation on the wire, which would be 95%, than you would end up with a length of 259.5', which is shorter. Now if I use the 1020 divided by 3.678 = 277' X .95 = 263.5', which is very close to the length that I arrived at through trial and error. I have a two core 4:1 current balun that I built and I will try it and will run the same scan on with my antenna tantalizer. Also as I mentioned before I also have a 2.5:1 UN-UN balun that I built that I will try too. I have a MFJ -854 and will check the current on the outside of the coax with each balun. I know that open wire is the best way to feed a loop antenna, however, there is no way to get it into my shack. I have read where some use ladder line to a 4:1 balun and then coax into the shack, but the length of coax must be very short. I can't do that either, as the coax run through my house to the shack is about 55 to 60'. Once I have evaluated all of the baluns, I will post the results. Everett N8CNP In a message dated 3/22/2015 12:05:46 P.M. Central Daylight Time, SkyWires@yahoogroups.com writes:

Everett, from the info you put on the files section of the group, it appears your loop is too short. The frequencies of lowest SWR are too high. If you take the standard formula for loops, 1005 divided by frequency, then 1005 divided by 3.6 MHz is 279-280 feet. While this formula is a "ballpark" it is not accurate. In reality the size of the wire, location, height above ground, and more all affect the length. So you may need more wire not less. Many builders have found 1020 to 1040 divided by freq is a better length for their location and installation.
Often the published / recommended lengths are for the phone bands not CW or multi-mode operations, For instance, 1005 divided by 3.9 MHz is 257 feet, closer to your 264 feet. Short length will cause all bands above the fundamental to show lowest SWR at much higher than even integer multiples due lack of end effect.
Loops should be fed with baluns with two cores, one at 4 to 1 or 6 to 1 and a second with a 1 to 1 balun connected to the feed line. This will not only do the impedance matching but

also reduce the currents on the outside of the coax. Careful with Sevick's designs as many were UN-UN designs not balanced to un-balanced. Also he did not use separate cores.
My loop is 274 feet but I feed with parallel feed line, a 1 to 1 balun and short coax to matchbox. So my length is not so critical as would be with coax feed line. Actually I just added wire connecting the ends of my 80 meter Inverted Vee and raised the whole antenna as high as possible above ground. Mine is at top of 12 meter bamboo poles.

Hi Tom, VK4ATH,
Yes that is a good setup with your loop. I also have 300 ohm line which I use but my Dentron Tuner had no Balun so I use the external balun and a 10 foot RG-213 coax to the tuner. The loop is on a 10 meter bamboo pole at the top of a 60 foot hill and the loop runs down over the hill, which is a steep drop off, to 3 12 meter bamboo poles on the lower land area. The loop is pointed North from the feed at the top of the hill. Works very well.
I also have an 88 foot inverted "L" fed with 300 ohm line,at the top of the hill also on a 12 meter bamboo pole, with the center feed at the top of the pole. Bottom of the vertical section is horizontal about 8 feet. Some times the "L" is better than the loop and other times the loop is better. Nice to have the choice. I use it for 80 to 20 meters.

Dr. Don HC4/W4BWS

4543. Re: [SkyWires] Just Installed a loop

Yahoo group: SkyWires
Date: 2015-03-24 00:06:41 UTC
From: Everett Sharp
Topic: 4531 Message: 4543

Hi Don,

I thought about what you said about the higher bands not being in resonance with the 264' length that I am currently using. So I went back and looked at the saved sweeps I did with the different lengths. After looking over the data, it looks like the 275' length might be a better choice. Here is the data:

Band MHz SWR
80M 3.579 1.12
40M. 7.176 1.77
20M. 14.122 1.97
17M. 17.67 1.92
15M. 21.201 1.71
12M 24.666 1.83
10M. 28.32. 1.84

Based on the data above that puts everything in band, with the exception of 17 and 12 meters, which I will use very little anyway. One other thing that noticed is that the impedance at all of the points of resonance varied from about 24 to 38 ohms. So before I do anything else I will see what I get by changing the 2.5:1 (50 to 125 ohms) balun to a 4:1 current balun (50 to 200 ohms).

I will be out of town most of the week, but will dive into looking at the various options I have over the week-end. I will report back once I find the best options.

>
> Yes, as I stated the formulas are ballpark and every real installation is unique.
> The reason I said it was short was not the freq of low SWR but the fact that the lowest SWR on all the higher bands are way above the ham bands. This says the antenna may be too short. If the SWR on 80 was at 3.550, the other bands would be lower SWR closer to the ham band.
> However when I used coax to the loop I adjusted so all the SWRs were under 3 to 1 at the band center, except 80 as I only operate 3.5 to 3.8. Then the tuner would take care of the final tuning.
> Yes the long coax run would be difficult for 450 line. Though the losses on the higher frequencies will be noticed with coax. Maybe a remote tuner where the coax enters the house and 450 line to the antenna from there. That may make as much as 6 db improvement on some bands. The coax loss would be minimal and more RF would reach the antenna.

From: Evan Rolek
Topic: 4531 Message: 4546

Fellow enthusiasts,

I use fiberglass poles to support my loop antennas in some of the corners. They are attached to trees, and have marine (Harken) pulleys at the top. I also have some HV hotsticks that I use for antenna work, they're all 40 ft long. I paint the poles flat black to resist UV, and then sometimes some camo colors to blend in. Some have been up over 10 years. Only failures are due to trees coming down in a storm. The telescoping sections that I use are from Max Gain Systems, a great company.

Dr. Don

You mentioned using 12 meter bamboo poles. Can you tell us more about them?

- What diameter did you acquire?

- What method did you use to plant them in the ground? cement?

Bamboo might be difficult here in Minneapolis Minnesota USA. I'd have to research bamboo at -25F.

I see you are an expatriate in Ecuador running a clinic . . . Thanks,

Terry KD0UTQ

Terry,
I have the poles here in Ecuador but it would be very costly to ship to MINN.
They use the poles here to do all kinds of construction, as scaffolding and as supporting structures.
Complete houses are made of bamboo and last for many years and have low cost upkeep. They also split the bamboo into thin strips but still connected to make a flat sheet. They use this for walls. Many cover them with chicken wire and cement then paint. Many buildings have been up over 50 years using this construction method.
Standard pole length is 10 to 11 meters. They are about 5 to 6 inch diameter at the base and 4 to 5 at the end.

Bamboo is actually a grass. Very strong and weathers well but subject to rotting if not able to dry.
Therefore, I use 4 inch drain PVC pipe 3 meters long with one meter+ in ground filled with a long piece
of steel re-bar and concrete. I also have concrete in hole around the PVC. The bamboo is mounted on the PVC, after curing for a week, using Monel adjustable hose clamps. They are available at marine stores. Stainless may be better but not available here in Ecuador. The monel resists rusting. I place a small rock under the bottom to permit drainage and coat the poles with 2 good coats of UV resistant varnish. You could also coat them with polyurethane or glass and epoxy. I also put a PVC cap on the end of the PVC and the top of the poles.

I mount pulleys at the top of the poles with ropes so I can pull up antennas. Mine have been up 5 years and still look good and function very well.
You may be able to find them in Alabama or other southern states. I used to buy smaller poles for making quad antennas in Alabama back in the 1970 and 80s.
But for the cost and long life I would check with the fiberglass supplier near Atlanta, I believe, as he has poles that telescope and go to 40 feet. Max Gain or something like that is the company. They make the fiberglass poles for the hex beams also.
Thanks for the note about our clinic here. It is very rewarding to help people regain and stay healthy with out drugs and at low cost using local herbs and foods. They average family here lives on $350 to $500 a month which does not leave much in the budget for Doctors or drugs. However food here is very reasonable and healthy, no GMO and right from the field to the table.
My wife and I live very well here on $900 to $1200 a month including building our home over 4 years. 1150 SF (12 X 9 meters) for about $40000.
We live on Soc Security very well here. The donations we get from the

patients helps keep the clinic open and clean. I wrote a book 3 years ago which I sell on the internet and shortly on Amazon, Retire in Ecuador on $30 a Day. It explains much of the reasoning for the many folks moving to Ecuador and how to do the planning for such a move.

I hope this has been helpful.

73 and God Bless

Dr. Don HC4/W4BWS

4550. Fiberglass poles for supporting horizontal loop antennas

Yahoo group: SkyWires
Date: 2015-03-25 04:41:39 UTC
From: Evan Rolek
Topic: 4531 Message: 4550

In response to some off-list inquiries, let me make a few comments about why I use fiberglass poles attached to trees for supporting my horizontal loop antennas.

By proper attachment, I can now do all lowering and maintenance activities from ground level. In addition, I can lower the pole itself from ground level should that ever be required.

The poles are virtually impervious to weather conditions. Rain, ice, and snow have no effect on the material. Painting them reduces the effect of UV rays and I've seen no deterioration in over 10 years of use.

They can sustain a large amount of flexing so that, even with stretchable truck tie-downs (and bungee cords) easing the load on the support cords, they resume their pre-flex shape after the source of the flexing is removed.

The fiberglass is easy to work with and, should one section break, it alone can be replaced without sustaining the added cost of replacing the entire length; I had to do this once when a tree fell down on one of my installations.

They are readily available (Max Gain Systems) and reasonably priced, even with shipping charges.

They are electrical insulators and have higher insulation resistance than wood, bamboo, etc. and have no observable effect on RF in the 1.8 to 30 mhz region.

By using stainless steel hardware exclusively, and marine grade pulleys (Harken brand), I consider the installation to be permanent to the extent that Mother Nature allows.

They can be easily painted to blend in with surroundings and thus result in "happy wife, happy life". I've not seen any deterioration of the paint and thus have not had any maintenance issues.

But here again, one size does not fit all. While fiberglass poles have worked well for me, they may or may not meet your requirements. I basically use telescoped poles, with ends slit and stainless steel hose clamps applied, for the basic installation. For assistance with stringing the wire, I sometimes use the fiberglass hotsticks which can also be used to trim tree branches. Since they are designed for rapid extension and retraction, they make excellent Field Day antenna supports as well.

Overall, I'm very pleased with my horizontal loop antennas and I hope that you are too. Let's all enjoy ham radio.

73,

Evan, K9SQG

From: bob engle
Topic: 4531 Message: 4551
Attachments: 1 described; binary payloads are missing from this source WARC

let me try this as an attachment
Scans of 80 meter loop fed with 300 Ohm ladder line fed direct and with a 4 to 1 balun
if this doesnt work I will post as a picture pleas let me know

Note: I would love to have access to 12 meter Bamboo!But I make do with the fiberglass poles which support the loop and double as my flag poles.73Bob

Hi Evan,

Could you post some photos of how you are using the fiberglass poles?
I am not deciphering what you are saying as to how they are installed.

Thanks for your time.

Thank you Even.
Winter? What's that ?
I think it depends on where you are at, 60 years in AZ WITH 30 in Phoenix and 30 up on high desert near Petrified Forest.
Very different worlds in same state.
I now am living in warm winter Michigan, I prefer winters here to winters in northern Arizona as it is MUCH warmer even with (for the most part) more snow. (I did get stuck in Flagstaff Hospital for 6 days in 2010 when 5 feet of snow fell in about 9 hours!)

Adrian and the group,

Attached to this email are four pictures of how I attach fiberglass poles to trees, along with a close-up of some hardware alternatives. Due to AOL formatting issues, the pictures will not likely come through. Hence, if you contact me off-list, I would be happy to send them to you directly. I apologize for the inconvenience.

Too, I'd like to hear of your experiences and how the techniques could be improved.

73,

Evan, K9SQG

4561. 40m - 10m Delta Loop skywire

Yahoo group: SkyWires
Date: 2015-03-28 19:47:05 UTC
From: helectrojo@...
Topic: 4561 Message: 4561

Hello everyone,
Great to find this group! Hope to get some answers to my questions related to a horizontally placed Delta Loop antenna

Together with some friends we want to experiment with a Delta Loop with all three of the corners attached at around 9m above ground - I guess this is what is called a skywire delta loop antenna - :)

I found this plan for a Delta Loop
https://rsars.files.wordpress.com/2013/01/40m-10m-delta-loop-antenna-gu3whn-iss-1-3.pdf
https://rsars.files.wordpress.com/2013/01/40m-10m-delta-loop-antenna-gu3whn-iss-1-3.pdf
and I was wondering if the geometry and the way it functions will be the same in case we transfer the design fully to the horizontal plane. We plan to use a 4:1 balun.

My questions are:

a) Does a skywire antenna changes polarization depending on the position of the feed, the way a Delta Loop does?

b) Are 9m a good height for this antenna?

c) Can you suggest of any similar design that we could implement -without the use of ladder line if possible-

Many thanks in advance
iordanis

Iordanis, welcome to the group.
I am sure there many on the list that can answer your questions.
My answers are:
1. Horizontal the antenna will be basically omni-directional with minor lobe distortions.
2. The feed point does not make much difference whether it is at a corner or middle of one side of loop when horizontal.
Feed location may make some small changes in the minor lobes.
3. The antenna pictured is vertical mounted but horizontal polarity due to the feed point. It is bidirectional some what at right angle to the plane of the antenna. But due to the low height above ground it tends to be more omni-directional at the lower frequencies. When mounted horizontal it becomes more omni-directional.
4. You will need a matchbox to tune out the reactance in the coax. The coax may see high impedance at the antenna on some bands, therefore losses will be higher on the higher frequencies.
5. The varying impedance and high loss in coax is why these antennas are usually fed with parallel feed lines for multi-band use.
6. 9 meters is a good height, 15 meters would be better of course. You have to do with what you have. On 80, 40 and 30 meters it will have a high azimuth angle for max lobe. But it will still produce some DX contacts.
7. There are many various loop installations. But basically all are similar to the one shown on the web page.
Some use automatic tuners at the feed point, no balun needed and thus lower coax loss. Others use parallel feed line to a tuner for lower losses. Which compromise you must decide that fits your needs.
8. A 142 foot loop may not do well on 80 meters since it is close to a half wave loop. Thus it may have very high impedance and some tuners may not match the feed line to the transmitter. However if the coax is a odd multiple of a quarter wave X velocity factor at 3.6 MHz it may bring the impedance down to a impedance the matchbox can handle.

I hope this is helpful

I built one with out ladder line and love it. Here is a u-tube of the idea.
www.youtube.com/watch?v=SOvhetU1_ps
I made it 80M size then tuned it to the center of the 20M phone band, here
are the numbers
http://i1102.photobucket.com/albums/g453/KD0ZZ/80MLoop_zpsa6e4cfe7.jpeg
I also used a 4:1 balun and here is a little information on the development
of it.
http://i1102.photobucket.com/albums/g453/KD0ZZ/Balunjpeg_zps41dd0ff6.jpg

4564. New Operator, first antenna

Yahoo group: SkyWires
Date: 2015-03-31 04:08:36 UTC
From: slr_65@...
Topic: 4564 Message: 4564

Hi Guys,

New operator here, I took my Tech test in Feb and my General in March. I have an Icom IC-730 but haven't got an antenna up yet. I've been pacifying myself with some local QSOs on 70cm with a HT.

I need to get an antenna up, but a tower isn't feasible right now. On offset feed Windom style would fit, but I've heard/read good things about the loops.

I do have room for an 80 meter loop, I'll probably only get it about 25' high though.

The feedline path would be 75-100'.

I recently purchased a Dentron MT-2000A antenna tuner.

The specs say:
Input impedance: 50 ohms (resistive)
Output impedance:
Coax - 50 ohms nominal; may range from a few ohms to a high impedance.
Long wire - either high or low impedance
Balanced line - 75 to 600 ohms

I notice it has a balun on the schematic and indeed there is one in the unit encased in a plastic container.

I don't know whether it's a voltage or current balun though and I don't know it's ratio.

Sooooo....

Set four poles so 65' of wire is on each side.

What type of wire for a long term installation?

What to use to fasten the wire to the poles, just your basic ceramic egg insulators?

How to join the ends to the feedline?

External balun, or use the one in the tuner?

Feedline, I'm assuming 450 ohm twin lead?

Any help, direction would be appreciated...it's time to get an antenna hung and get the HF rig fired up!

73's

Steve
KE0DBH

Many thanks to both of you for the quick reply!

Probably early next week I will be able to test my setting and find out how it actually behaves on the air, one more question on what should I expect in case I will feed the antenna through a 4:1 balun, you think it will ease a bit the tuning through the antenna tuner or should I use ladder line?

Best regards and many thanks again,
iordanis

4566. Re: [SkyWires] New Operator, first antenna

Yahoo group: SkyWires

From: WA8JXM
Topic: 4564 Message: 4566

Steve, first of all, welcome to HF.

FWIW, I operated several years with dipoles with the center only up 20' and the ends just head high. That worked out decently.

Last summer I finally put up a tower and several 40' utility poles and put up 650' loop. It worked okay but no better than the inverted vee up on the tower. So I cut it down to a 160m OCFD..

As for the loop, some sources say use a balun, others like the ARRL Handbook say do not use a balun. Try it either way.

Some loop designs say feed it directly with coax and no balun, others say to use ladder line or open wire. Take your choice.

That's the great thing about antennas, they are still one way that we can homebrew and experiment.

Antenna wire? 14 or 16 gauge hard-drawn copper, copper clad steel wire, or buy a 500' roll of THHN (12 or 14 ga) at Lowes or Home Depot.

Insulators? Although the egg insulators will work, I would use regular antenna insulators not the egg type.

Connecting feedline to the antenna? Use an insulator, secure both wires securely and either use crimp terminals or solder the connection or both (bare crimp terminals and then solder. However, when you are first putting it up and may be adjusting it, I would use either the crimp terminals or the twist terminals used for household wiring.

There are no hard and fast rules for antennas they are a great area to experiment with. That 20' high dipole I mentioned? I even used it on 160 and made some contacts and I've worked Australia on 30m with a 20' high 40m dipole, coax fed. I will mention that for poor, compromise antennas, digital modes or CW work best.

73, Ken WA8JXM

I dont remember, what type of radio do you have?? If it has a built in tuner it should be OK as is if balun is at feed point and you use coax. With ladder line you need a 4:1 at the indoor tuner . Some people have a problem feeding ladder line into the shack.

For you size loop , as has been said any 12 or 14 gauge wire will be fine.
If you can find some scrap plastic, (polycarbonate) it is easy to make
you own center insulator.

http://i1102.photobucket.com/albums/g453/KD0ZZ/300OhmMount.jpg

My picture show a 300 ohm one but just adjust the clamp screws for 450 ohm.
Check out some of the other pictures and you I use split bolts for attach
adjustment. You can get them at any home depot type store or local hardware
and make adjustment very easy,
The balun in you tuner should be fine, if it cant go down to 1:1 SWR you
can build your own. Looking at my album you can see how easy it is.
Don't worry about height of the wire, just so you don't knock you hat off
while cutting the grass it will work, but then higher is better.

From: Evan Rolek
Topic: 4561 Message: 4569

I prefer to use ladder (window) line with a link coupled tuner, or dual roller inductor tuner, in the shack. With a balun at the antenna, the ratio will not be correct for all bands. If it is ok for the bands of interest, then yes, it could be used. But, for example, if the antenna is 110 ohms resistive on the fundamental, that brings it down to 27.5 ohm, outside the range of some tuners. Using window line to the shack solves a lot of problems. Too, for me, I find 300 ohm transmitting twinlead is a better match for my bands of operation. Lower visual cross section which xyl likes.

73,

Evan, K9SQG

Subject: [SkyWires] Re: 40m - 10m Delta Loop skywire

Many thanks to both of you for the quick reply!

Probably early next week I will be able to test my setting and find out how it actually behaves on the air, one more question on what should I expect in case I will feed the antenna through a 4:1 balun, you think it will ease a bit the tuning through the antenna tuner or should I use ladder line?

Best regards and many thanks again,
iordanis

I have found in over 20 years of experimenting with loops that #13 stranded copperweld, insulated, is about the best antenna wire I have ever used!

From: everettsharp@...
Topic: 4573 Message: 4573

I just removed a file that I posted on 3/22/15 and replaced it with a new article with data compairing a 2.5:1 vs a 4:1 balun. Based on this experiment it looks like the 4:1 balun is a better way to go, as it improved every band, with the exception of 80 Meters. I will later add more wire to bring it to 275'

Ladderline down to shack

Window line works good and is easy to work with

Upper few inches changed to some added speaker cable (soldered to the window line and heat shriked) ... reason ... more flexible at the point were the line may flap around in the wind

Homebrewed centre insulator (made from some plastic I had laying around

Egg insulatos in the edges

....

Do not use the best wire .. use the cheapest ... and make your tests with scrap wire ... then when you found your permanent installation you can change to some real good antenna wire

....

Make the ladderline several feet longer as needed ... and you have trouble with tuning on some of the higher bands you can change the ladderline length

MAKE NOTES!!!!!!!!!!!!!

....

With changing ladderline and loop length I could find a "sweet spot where no tuner is needed on several bands (just the balun inside the tuner but the other parts are bridged)

Welcome abord :-)

You haven't stated the length of the feed line from your tuner to the loop.
If more than 50 feet, I would use parallel feed line from the loop to just outside the ham room. Then the 4 to 1 balun and a short coax into the tuner. Your losses in the feed line will be much lower in the parallel line than in the coax.
Depending on your tuner being able to, on 40 and 30, match the transmitter to the coax, the loop should work well 40 to 10 meters.
At low height 1000 miles on 40 and longer on other bands should be normal.
Some nights depending on noise and propagation you should be able to work DX. Dx on 20 to 10 should be regular depending on propagation.

It appears the 4 to 1 balun brought 30 meters down close to 3 to 1 and thus
it is usable with a tuner.
Thanks for the data dump.

Don,

Unfortunately I have about 40' of RG8X coax that runs from my attic to my ham shack and another 40' of RG8X to the 4:1 balun, so ladder line, or 300 ohm wire to, the 40' run to the shack might not be the best way to go. However, I will increase the length from the current 264' to 275' based on a previous scan that shows 40 meters and above bands closer to resonance at, or near the center of each band. It doesn't help 80 meters, but I don't use it much anyway.

Well 300 ohm, or better open wire parallel feed line, from antenna to the 4 to 1 balun and the 40 foot coax to the shack would reduce the loss in the coax to one-half . That could be 3 to 6 db depending on the band and the impedance at the loop feed point. Of course the loss in the 40 feet can't be avoided but it can be reduced as much as possible. Remember the high SWR in the coax at the antenna is repeated every half-wave along the total coax run.
I will be glad to see the next results you get by adding the short wire to the loop.

4581. Re: New Operator, first antenna

Yahoo group: SkyWires
Date: 2015-04-01 04:09:14 UTC
From: slr_65@...
Topic: 4564 Message: 4581

Thanks Guys! Both for the advice and the welcome!

I should clarify, I'm a returning amateur - I had my novice ticket at 13, my Tech at 15 and my General at 17. Unfortunately as I went to college, the service, got married, etc. I got away from radio and let my license expire. When I was a teen my brother was also an amateur, we had a full Yaesu FT-101E station but only ran 20 and 10 meter, the DX was GREAT in those bands in the late 70s / early 80s!

So, this is my first foray into a multiband wire antenna, though I have experimented with dipoles in the early '80s.

OK, it looks like it's shaping up to be a square about 65' to a side. Normal insulators on the corners. What to use for the four poles I've yet to decide. I'm thinking 2" plumbing pipe, or possibly even emt conduit or exhaust tube may work. For the first run I'll use some 12 THHN copper I have, if I'm liking how it works I'll switch to the Wireman 13awg wire. To feed I'm thinking 450 ohm window line. For a center insulator I'm thinking a Ladder-loc center. I'm having some vision issues so working around saws and stuff probably isn't a good idea and the ladder-loc is only $15. Run the 450 ohm to the tuner. Doing some research it seems these tuners had 4:1 voltage baluns in them, I may look at putting in a 4:1 current balun. Then a short piece of coax to the rig...sound like a plan?

The only real question is what to use for the support poles. I have a friend with a 30' extension ladder, so I'm thinking something at about 25' is in order, if we keep the ladder fairly vertical then the force on the pole won't be as much, so 2" pipe should suffice...may have to just put one in and see.

Thanks!

Steve

Hi Sigi,

The top band I'm looking at is 10 meter. I want to have access to all of them (I've worked hard for my license, I want to take advantage of every privilege it extends me), which is why I bought the Dentron tuner, they appear to be good units that can tune most anything.

If you use plastic pipe, 3 ten foot sections, overlapped about 2 feet and bolted together should work. Start with 3 inch at the base. Consider a wood plug at the top with a PVC cap on the top section. Then you can install a pulley to hoist up the antenna and a eye screw for the back guy. A set of three guys at the top of the 20 foot level, actually 18 feet, and a back guy at the top to offset the antenna wires should support the mast. Above 20 feet the pole will certainly sway in the wind.65 feet of wire will pull the mast a good bit.

I don't have the room or desire to guy the poles, I'd rather pay a little more and have them self support.

This site shows a 2" sch 40 base with 1-1/2" top section that self supports at 35 feet. I would think I could drop the height back to 25 feet and keep it all 2" and be sturdy enough to put a ladder against.

I would not want to climb a ladder that is standing against a plastic tubing ... no way ... but if you add some pull-eyes at the top you do not need to climb a ladder ...

The rest seems to be a good plan

... I do not like the ladder lock thingy ... reason is that the line may break at the entry point of that ladder lock ...

The window line (and the antenna) WILL swing in the wind and so I added some very flexible speaker cable at the upper end

Topic: 4564 Message: 4587

Hi Sigi,

I have an Icom IC-730 for an HF radio and it only goes to 80 meter, and my lot size only allows an 80 meter loop, so it'll be 80-10 I'm looking for.

I agree, I haven't seriously looked at pvc, it was a member suggestion here. The link I gave uses 2" sch 40 steel pipe with 1-1/2" for the last section to make a 36' tilt up self supporting pole. That design is pretty common, I've found it on several sites and in several forums and no one seems to have had any trouble with it, though they are tilting it to install the antenna where I'll probably be keeping it shorter and working off a ladder, though there is a tree trimming place in town with a bucket truck that other amateurs in town have used for antenna work.

73's

Steve

Put a ladder against a 1-1/2" pipe and climb it? You must have a death wish, sir. A ladder against a single narrow support like that will likely twist sideways once you get up it. Not that I would trust the strength of the mast to support me on a ladder either.

The design of that mast looks good except the use of black iron pipe. Water pipe, etc. is soft iron and should not be used structurally. Structural steel tubing (DOM) is much stronger. It's also available in different thicknesses so that you can get a good fit slipping one piece inside the other.

I have a somewhat similar design made out of wood, a 24' 6x6 cradled between a pair of 4x6's and a 16' 4x4 spliced on top

Black iron will work but why bother with a inferior product. Use just standard steel and a coat of paint. Scd 40 steel is strong enough for any wire even a small beam.

http://i1102.photobucket.com/albums/g453/KD0ZZ/TiltOverB.jpg

This is a picture of mine , it now supports one leg of a 160 delta loop and a hex beam. Other pictures show a yagi but now is a hex. Also is a sketch on a smaller tilt over in my album. Plain steel is stronger and with paint you don't need the expense of galvanized and if you want to weld on it you don't have the problem of galvanized. My larger tiltover requires no welding and can be scaled down for 2" pipe.
When you order stock make sure you know the difference between 2" pipe and 2" tubing.

Hi Rich

How do you paint the inner side of the tubing??

Rag soaked in paint on a pull through string? Run paint down it whilst rotating it? Most tube from the steel mill is covered in oil, so it would need a thorough internal de-greasing first fo there to be much point in it. Even left bare it would take a LONG time to internally rust significantly though.

I had a steel tubing mast years ago (when i was young in cbers days) ...

In around 25 years it was rusted from inner to outer wall (outside looked
like brand new)

And hwne cutting it down it was VERY THIN on some areas!!!

No not an aprils joke

Was a galvanized steel tubing but the inner side rusted away still the wall
was thin like paper

4593. painting inside of metal tubing

Yahoo group: SkyWires
Date: 2015-04-01 18:22:23 UTC
From: Evan Rolek
Topic: 4564 Message: 4593

I have had situations where I needed to paint the inside of a long piece of pipe. I had some rubber caps that fit over the ends. I capped one end, with the plastic cap and duct tape. Then at the other end, I poured in a quart (?) can of Gunk degreaser. Capped that end again using duct tape. Then I tilted the pipe back and forth while rotating it a few degrees each time. Then I drained off the used Gunk, opened both ends, and flushed the pipe with a water from a garden hose. After letting it dry a day or so, I capped one end like before, poured in a quart of Rustoleom paint designed for rusty surfaces, and sloshed it around back and forth repeatedly. Drained off the paint, saved it, let the first coat dry, and then repeated the process twice more. Did it work? Not sure, but the pipe was used outdoors to support an antenna and it lasted 25 or so with no sign of degradation when I cut it down due to changing QTHs. Your mileage might vary.

Hi Guys,

The choice of materials is simply what's available easily in town, and I live in a small town so the selection isn't big, basically galvanized and black iron pipe, sch 40 up to 2-1/2". They also stock a small supply of flat iron, angle iron and some square and rectangular tubing.

They said the galvanized is plumbing pipe and the black iron is gas and steam pipe (many houses here still have boilers), they both conform to the normal sch 40 dimensions. They are both available in 10' and 21' sections.

Climbing isn't a big issue for me, my Dad was a lineman and I played with his hooks climbing a security light pole in the backyard all the time when I was a kid and up until a couple years ago I worked in a power plant with 30' catwalks accessed by straight up ladders.

I'm sure 20' or so of 2" sch 40 would stand up to having a ladder put against it, remember most of the weight is going down on the ladder, not sideways on the pole.

The ladder could twist on the pole, but if one kept it fairly vertical it would minimize that and one could even add a couple arms to the top of the pole to support the width of the ladder. The ladder I have access to also has out riggers you can pivot out to help stabilize it, so choose a calm day and I'm not too concerned with climbing it.

There's also a tree trimming service in town with a bucket truck and a couple other operators in town have hired them for tower work and they're reasonable. All four posts would be easily accessible for a bucket truck, so I may see what they'd charge for a couple hours of bucket time.

Guys,

I just deleted the file that I had posted in the files section "80 Meter Horizontal Loop" and replaced it with a revised version that includes my final addition with a length of 275' and a 4:1 balun. I am very please with the results and hope the information will be of some value to the members on this list.

In your last "sweep" is a typo

You wrote 80 40 20 30 17m etc

It should be

80 40 30 20 17 etc

Accidently 20 and 30m are interchanged

Dg9bfc

Sigi

Ps ... I have same setup but with a 160m loop

4601. Re: 40m - 10m Delta Loop skywire

Yahoo group: SkyWires
Date: 2015-04-04 08:36:22 UTC
From: helectrojo@...
Topic: 4561 Message: 4601

Hi everyone again!
Couldn't wait till early next week, so I experimented a bit with the antenna setting by following some of your advices with the below results.

The readings are from my BlueVNA PRO and shows the lowest point on each band.

Total length of the loop 45m (147.6 feet), 9m above ground, no matching (neither BALUN or ladder line)
Band MHZ Z SWR
40m 6.8 61 1.26
30m 10.4 15.2 8.4
20m 13.6 105 4.28
17m 18.9 5.5 10
15m 20.1 55 2.8
12m 26 14.5 7
10m 27 27.1 3.58

After the first readings we cut 110cm (3.6ft) of the loop wire, added a 4:1 BALUN and run the test on the VNA again

Total length of the loop 43.9m (144 feet), 9m above ground, 4:1 BALUN
Band MHZ Z SWR
40m 7.1 22 2.8
30m 8.5 18.8 10
20m 14.2 49.3 1.09
17m 16 326 7.3
15m 21 55 1.3
12m 23 15.8 3.2
10m 27.8 74 1.74

Now, the next question would be, should I cut the wire even more in my try to bring more to the center the 15m and 10m bands, or that will create more problems to the 40m and the 20m bands?
In any case I can tune the antenna on all the 4 bands by using the MFJ-962D, so do you believe is worth trying to adjust further the length of the loop wire?

In my tests I had easy contacts on 10m with AA1FB, KD8ZTO, N8EHP, CT5KJE from all of them I had good reports over 58 to 59 +20, with 80w on my side. If it wasn't the noise from the long range radar -most probably IRAN- I would be able to work many more stations.

As long as the transmitter will make a tuning match to the coax I would just use it and have fun.
The 4 to 1 balun is probably why 40 SWR is higher, but the antenna is quite usable as is.

My experience has been that a horizontal loop, as well as some other configurations, are not critically dependent upon SWR on any given band, fundamental or otherwise. With a loop antenna that is "way out of resonance" on the fundamental frequency, I've not been able to see any performance differences between that configuration and one that is resonant either on the fundamental or harmonic. This is based upon field strength readings in my shack as well as on the air reports. If there are differences, they would appear to be minor. Hence, if my tuner can transfer power to the antenna without much loss, it seems to be acceptable to my operations.

However, for those that are searching for the Holy Grail of antennas then yes, experimenting to find an all-band antenna that produces a 1:1 SWR on all bands, and all frequencies within a band, with no loss, can be fed with coax, doesn't need an antenna tuner, can be an educational experience that is also fun. Or one can just buy a commercial antenna that is advertised to have these characteristics (ooops, I was only supposed to say that on April 1).

Let's share our experiences and have fun with the hobby. I hope everybody has a safe, enjoyable Easter weekend.

73,

Evan, K9SQG

Subject: Re: [SkyWires] Re: 40m - 10m Delta Loop skywire

As long as the transmitter will make a tuning match to the coax I would just use it and have fun.
The 4 to 1 balun is probably why 40 SWR is higher, but the antenna is quite usable as is.

On Sat, Apr 4, 2015 at 3:36 AM, helectrojo@gmail.com [SkyWires] <SkyWires@yahoogroups.com> wrote:

Hi everyone again!
Couldn't wait till early next week, so I experimented a bit with the antenna setting by following some of your advices with the below results.

The readings are from my BlueVNA PRO and shows the lowest point on each band.

Total length of the loop 45m (147.6 feet), 9m above ground, no matching (neither BALUN or ladder line)
Band MHZ Z SWR
40m 6.8 61 1.26

30m 10.4 15.2 8.4
20m 13.6 105 4.28
17m 18.9 5.5 10
15m 20.1 55 2.8
12m 26 14.5 7
10m 27 27.1 3.58

After the first readings we cut 110cm (3.6ft) of the loop wire, added a 4:1 BALUN and run the test on the VNA again

Total length of the loop 43.9m (144 feet), 9m above ground, 4:1 BALUN
Band MHZ Z SWR
40m 7.1 22 2.8
30m 8.5 18.8 10
20m 14.2 49.3 1.09
17m 16 326 7.3
15m 21 55 1.3
12m 23 15.8 3.2
10m 27.8 74 1.74

Now, the next question would be, should I cut the wire even more in my try to bring more to the center the 15m and 10m bands, or that will create more problems to the 40m and the 20m bands?
In any case I can tune the antenna on all the 4 bands by using the MFJ-962D, so do you believe is worth trying to adjust further the length of the loop wire?

In my tests I had easy contacts on 10m with AA1FB, KD8ZTO, N8EHP, CT5KJE from all of them I had good reports over 58 to 59 +20, with 80w on my side. If it wasn't the noise from the long range radar -most probably IRAN- I would be able to work many more stations.

4605. Ladder Fed 160m 80m FWL with TS-590S internal ATU

Yahoo group: SkyWires
Date: 2015-04-20 02:41:29 UTC
From: contact001@...
Topic: 4605 Message: 4605

I recently acquired a TS-590S (just before Christmas) and was interested in how the internal ATU would handle the ladder fed 550' 160m FWL that I had up. Turns out the answer was "very well".

Previously, I had been using the balanced wire connection on an MFJ-941D Versa-tuner to connect an old Yaesu FT-707 with the homebrew 4" ladder line (made with 14 AWG THHN) that ran from there all the way to the loop feed point about 70' up (about 140' of ladder line). I knew I needed an alternative for interfacing the ladder line with the TS-590S' coax connector so I did a series of full range SWR sweeps with a Rigexpert AA-170 using various current baluns I had on hand connected to the ladder line , looking for a reasonable fit. The ratios tried were 9:1, 4:1 and 1:1, all Guanella type designs wrapped on ferrite toroid cores. The best single "all band" fit was the 9:1 three core current balun - not best for any one band, but best compromise for multiple bands with the aim of having "tunable" SWR for as much bandwidth as possible.

The 9:1 connects to the TS-590S via about 2' of 8x coax. The 4" open line goes from there across the basement ceiling, through a masonry wall & then up to the feed point. The internal tuner is able to find a 1:1 (or close to it) match for the vast majority of 160m -> 6m with only a couple of trouble spots in the 10m & 6m bands. I did experience some RF in the nearby computer speakers at some higher freqs, but wrapping their power & audio lines on a couple of ferrite toroids took care of that.

I later added a 290' 80m loop, hung slightly lower than the 160m loop fed by about 70' of 4" ladder line connecting to about 30' of 8x coax via a current balun. Trying different ratios led me to go with a 4:1 dual core current balun on that loop for best compromise for 80m - 6m. Between the two loops, the internal tuner provides full coverage of the amateur bands, no gaps. I have been very impressed with the TS-590S internal tuner. It consistantly arrives at good solutions very quickly.

Both loops were constructed from 14 AWG THHN/THWN and hung from tree mounted suspension points.

4609. Series antenna tuners?

Yahoo group: SkyWires
Date: 2015-06-01 05:35:15 UTC
From: slr_65@...
Topic: 4609 Message: 4609

Hi Guys,

My world is a bit turned upside down, due to an eye disease called Non-Arteritic Ischemic Optic Neuropathy I've been left with very low vision. I had it in one eye and it was only a 15% chance it would hit the other, but my luck didn't hold out, it struck and devastated the other eye a week and a half ago.

I was in the middle of refurbing an Icom IC-730 and getting a station put together.

With BIG fonts and Windows high contrast settings I can run a pc, and I can read somethings given some time.

I've decided to carry on with amateur radio. I bought a Kenwood TS-590SG on HRO's Dayton sale (just before this hit! I wanted to return it, but my wife said no - she'll learn to run it for me if I can't...I love that woman!), so I have it and I have a Dentron Super Tuner antenna tuner.

I was going to put up a horizontal loop, so I have the wire and center insulator plus some 450 ladder line. I didn't get the supports up before this hit though.

I have a 10 meter dipole up under the eaves of the house and with the Icom and Dentron I can tune to 20 meters with it, though I haven't tried the Kenwood yet.

We're still in shock, I'm taking a controversial high dose steroid treatment hoping to gain some vision back, so big projects are on hold right now, we may not stay at this location.

The perimeter of the house eaves would make a loop about 210', I'm thinking that would make the loop resonant around 4.8mhz. That's probably further out than the Kenwood's internal tuner can handle for 40 meter and higher, but I was wondering if I'd use the Dentron to get it resonant on 40 meter and then if the Kenwood's internal tuner would be able to match the harmonic bands? Is running two antenna tuners in series a problem if one is left set to tune the lowest band?

The loop will run parallel and near an rg6 quadshield cable tv line on the back of the house, so it may interfere, but I thought I would try it and see. If it does, then the backup plan is to cut the wire off the back of the house and run the antenna as a doublet, the legs would fold around the corners of the house though, however I would think the tuner should be able to still get a good match. Again, here it would be nice if I could set the Dentron to get a good match on 40 meter and then have the rig's internal tuner match the harmonics.

Not ideal, but I've been dealt a bad hand and am just trying to get on the air.

Any thoughts, suggestions, etc. welcomed...thanks guys!

Steve, KA0NEB

I have had good luck with the TS-590S tuner capabilites all by itself, working 160, 80 and 40 meter full wave loops. I think you probably want to use either internal or external by themselves. If the internal is not up to the task, you might want to consider an auto tuner like LDG for broader capability without needing to see dial or readout values.

Thanks Nick,

It may do it, I guess I just need to see.

I just have the Dentron with it's internal balun, if I skip it I'll need to see about a balun.

I'm really thinking this should work. The antenna and Dentron should just look like a tuned antenna I would think. Wouldn't it be akin to portable antennas with loading coils? I'm sure I've read where people have used tuners on loaded antennas.

It would just be nice to use what I have, guess I"ll just have to give it a shot and report back!

Thanks!

I think as you tweak one you have to re-tune the other. Remember that part of what the tuner is doing is matching up capacitance and inductance. When the "tuned" antenna (Dentron) change the other has to compensate. Likely a reiterative process that is a waste. Again, Why do you wanna run two tuners?

Hi Skip,

I've been hit by a devastating eye disease, I'm nearly blind. I can see big things and a computer with BIG fonts, but that's about it.

Trying to manually tune a tuner each band change would suck.

I want to run a loop around the house eaves, but since I can't vary the size of the loop it won't be resonant on a particular band, I think it would be resonant about 4.8mhz.

The loop would be 450 ladder line fed, so needs a balun, plus it's far enough out of resonance I doubt the Kenwood's internal tuner could tune it.

The Dentron has an internal balun, plus I'm sure it could tune the loop to 40 meter.

My hope is that I could tune the Dentron such that the loop is resonant on 40 meter, and then that resonance would carry through to the harmonic bands, if a slight touch up is needed I'm thinking the SWR would be close enough that it would be in range of the Kenwood's internal tuner so I woudn't have to manually tune for band changes.

I'm thinking it should work, I guess we'll just have to try and see.

Sometimes two tuners are warranted. Why? Because one tuner lacks the matching range needed and can "get things close" but not "right on". However, this is an emergency or quick fix until a proper tuner can be pressed into service.

I doubt that the situation described would be practical. On the 40 m ("resonant") band, if the tuner was doing it's job, it would NOT necessarily do that on harmonically related bands. On 40, it is compensating for the resistive and reactive components of the antenna being away from 50 ohms, pure resistive. On harmonic bands, or any other band, the resistive and reactive components of the antenna itself would change, thus invalidating the tuner's settings for compensating them on the other bands.

To look at it another way, let's say a rig has an internal, automatic tuner and it has tuned an antenna for a 1:1 SWR. Changing bands to another, harmonically related band, would mean that it would have to readjust the settings to get that same SWR value. Try it, you'll see what I mean.

Trust me, I'm no antenna guru. Maybe the real experts can correct the faulty logic above...

Thanks for the feedback guys! Sorry to be slow responding, I'm taking an experimental high dose steroid treatment for my eye problems and they're kicking my butt!

A friend loaned me a MFJ SWR analyzer, it's a lower end model, but you can hook a frequency counter up to it to find your resonant frequency, so I did some testing.

It sort of works. If I set my 10 meter dipole resonant with the Dentron on 40 meters it does carry through to the harmonics, but not well. Not near what using a tuned antenna would.

I found the spec in the new rig, it should match SWR from 10:1 down. I think with the Dentron set to resonate the loop the rest would be less than 10, so it may work.

However, I don't think it's the best approach I would like the loop for it's quieter characteristics, but I also don't like to have the SWR so far out and make the tuner work so hard. I think a doublet or something similar that I can get more resonant and that will stay reasonably resonant through the harmonics is a much better idea.

Thanks!

4617. Re: [SkyWires] Re: Series antenna tuners?

Yahoo group: SkyWires

From: Evan Rolek
Topic: 4609 Message: 4617

When it comes to SWR, especially manufacture specs, "it depends". Almost without exception, the specs talk about an SWR of 10:1, 5:1, or whatever, but that is only PART of the spec, and not necessarily the most important one a that. They typically talk about matching the resistive component of the antenna, NOT the reactive component, whether it be inductive or capacitive. Hence, selecting a tuner almost becomes a trial and error process. And when you ask them about the reactive specs, you'll often get a response akin to a pig looking at a wristwatch. So even if you know the resistive and reactive components of an antenna, for the bands of interest, it is still a chore to find out which tuner(s) will work for your particular installation. Sometimes asking other users can be informative.

My experiences have been that horizontal loops are much more forgiving of installation irregularities and are vastly easier to match on a broad range of bands. Then again, pursuing the Holy Grail of antennas (which doesn't exist, you know, an all band antenna that can be fed with coax, doesn't require a tuner, and works great for DX and local contacts, and is broad banded) can be quite educational and enjoyable through experimentation. Then again, if one is time limited, then doing some research to find out what is already known can be informative. It depends on one's circumstances and preferences. L. B. Cebik's (W4RNL, SK) writings relate computer analysis comparing a range of antennas including loops and dipoles, etc.; I'll let the data speak for itself.

I would love to play, but my vision isn't cooperating. Depending if I recover some I may or may not be able to keep working and keep the house. Until I know if we're staying here I don't want to do any large antenna projects. I just want on the air in HF.

I'm in a 1,100 square foot single story ranch house with attached garage and have decided to just run something around the eaves. That's not a lot of height and it's not a lot of length, though a 10 meter dipole I have up on it works well and the Dentron can match it to 20 meter (I haven't tried the Kenwood on it yet).

I liked the characteristics of a loop, which is why I was looking at putting up supports in the yard for one before my eye issues unexpectedly flared up. In that instance I could tailor the loop diameter to get resonance, but now that I can just basically loop the house I'm stuck with that diameter, which isn't going to resonate on a particular band, so I was hoping I could crutch the resonance with the Dentron. The testing with the MFJ was interesting, using the Dentron to set a resonance does carry through to the harmonics, sort of. You can definitely get points of lower SWR somewhere near the harmonics, but they're not great, they're just lower, and who says they'll behave the same when more power is pushed through. The MFJ says I can get a match on 40 meter with my dipole, but when tried with the radio it doesn't work. There's just a lot involved here and I think no hard and fast rules, trial and error is probably the only real way to know, but I'm not really up to it.

I do have the length for a dipole type antenna, though the legs will be folded around the house corners. I think the rig tuner should be able to handle that though.

A fellow amateur in town has a spiffy MFJ analyzer that tells you everything. I think I just need to put something up, analyze it and adjust. i.e. I think use 450 ladder line and center insulator, string as much wire as I can up, analyze it and see where I resonate, then adjust the length to get the resonance to a band I can harmonic off of. The analyzer should also be able to tell me the impedance so I know what ratio balun to get (this may be hard to calculate do to the low height and attachment to a structure from what I gather, so measuring it is probably the best approach). From what I gather, running the ladder line inside and then just a short jumper between the balun and rig is best, and it appears current baluns are preferred.

Sound like a plan?

Plans are good. But the poorest installed antenna give more QSOs than the best antenna on paper.

I like to do research and understand things but I'm a pragmatist as well. From my experiments, with stations within 2 miles, as well as those at distances up to 1,000 miles, I have observed no change in transmitted signal reports nor received signal reports between resonent and non-resonent horizontal loop antennas on the 40 meter band. At 12 ft off the ground, in the evenings on SSB, I've worked into Italy regularly, Canary Islands, France, former Soviet Union countries, South America, Alaska, etc. etc. The antenna is not supposed to work at all, let alone for DX, but I didn't tell the antenna that so it keeps on working. Yes, some antennas are sensitive to resonence, but the horizontal loop isn't one of them. Then again, I only have 25 years or of experience with this particular antenna so the jury is still out on this one, hi hi.

Hello Evan and all..

I also have quite a few years using a horizontal open-wire fed loop.(1100 feet long and =or- 35 feet above ground and I am continuously amazed at the performance be it local or dx. It is totally tree supported and at times can be quite maintenance intensive, but I still keep coming back to it as my goto antenna for the marginal signal contacts! The best part is that even with internal tuners in my radios it rarely will go unmatched , which continues to surprise me!!

From my experiments, with stations within 2 miles, as well as those at distances up to 1,000 miles, I have observed no change in transmitted signal reports nor received signal reports between resonent and non-resonent horizontal loop antennas on the 40 meter band. At 12 ft off the ground, in the evenings on SSB, I've worked into Italy regularly, Canary Islands, France, former Soviet Union countries, South America, Alaska, etc. etc. The antenna is not supposed to work at all, let alone for DX, but I didn't tell the antenna that so it keeps on working. Yes, some antennas are sensitive to resonence, but the horizontal loop isn't one of them. Then again, I only have 25 years or of experience with this particular antenna so the jury is still out on this one, hi hi.

That's not a lot of height and it's not a lot of length, though a 10 meter dipole I have up on it works well and the Dentron can match it to 20 meter (I haven't tried the Kenwood on it yet).
>
> I liked the characteristics of a loop, which is why I was looking at putting up supports in the yard for one before my eye issues unexpectedly flared up. In that instance I could tailor the loop diameter to get resonance, but now that I can just basically loop the house I'm stuck with that diameter, which isn't going to re sonate on a particular band, so I was hoping I could crutch the resonance with the Dentron. The testing with the MFJ was interesting, using the Dentron to set a resonance does carry through to the harmonics, sort of. You can definitely get points of lower SWR somewhere near the harmonics, but they're not great, they're just lower, and who says they'll behave the same when more power is pushed through. The MFJ says I can get a match on 40 meter with my dipole, but when tried with the radio it doesn't work. There's just a lot involved here and I think no hard and fast rules, trial and error is probably the only real way to know, but I'm not really up to it.

>
> A fellow amateur in town has a spiffy MFJ analyzer that tells you everything. I think I just need to put something up, analyze it and adjust. i.e. I think use 450 ladder line and center insulator, string as much wire as I can up, analyze it and see where I resonate, then adjust the length to get the resonance to a band I can harmonic off of. The analyzer should also be able to tell me the impedance so I know what ratio balun to get (this may be hard to calculate do to the low height and attachment to a structure from what I gather, so measuring it is probably the best approach). From what I gather, running the ladder line inside and then just a short jumper between the balun and rig is best, and it appears current baluns are preferred.

What I've read suggests that on window line fed loops you can tune it to something above (in freq) what it's cut for but going the other way doesn't work well.

Here's an idea...

I think the dipole with the bent corners is fine and with a total of only 120' and can cover 75m and higher. You could use the same feed point and run another pair of wires 65' (total) 5" away from the original and you have a parallel dipole that can be trimmed to be resonance on 2 bands. Go another 4" away with a 33' wire and you have 20m also. This can be fed with a single coax and no balun and single tuner.

Look out for gutters and edge flashing metal.

OK, got play time tonight...it works on a 10 meter dipole!

I have a 10 meter dipole up on the side of the house, no balun and coax fed, only about 12' high.

Using an MFJ SWR analyzer I found I could get it to match on 20 meter and testing with my old Icom it did work.

Tonight I hooked up the new Kenwood. With the antenna hooked directly to it it couldn't find a match. BUT with the Dentron hooked up and set resonant on 20 meter and hooked to the Kenwood the Kenwood's tuner WAS able to easily find a match for every band below 20!

In fact my very first contact was with the CZECH REPUBLIC! It wasn't pretty, but I did make it through the pile up and got a confirmation! I was thrilled!

If I can do that on 16' of wire I'm encouraged that running more wire will only get better.

It's not working as I had originally thought, getting resonant on a lower band doesn't carry good resonance through to all the harmonics, but evidently on the 10 meter antenna at least, it does carry through well enough to make the internal tuner work!

I can live with the way it works now, 20 through 10 with no manual retuning. I hope adding more wire will get more signal through and improve performance, and if I can maintain the no manual retuning that will be huge.

I'm thinking I'm going to run the loop around the house and see what happens. If that doesn't work we'll shorten it up until it does work, hopefully I can get 40 meter and down working this way.

Oh, though I'm still figuring it all out, which is hard with low vision, I'm LOVING the new Kenwood!!!

I have a horizontal loop (somewhere around 500 feet of wire) fed with about 35 feet of 450 ohm window line to a home made 4:1 balun at the shack end of the window line. From there maybe 20 feet of coax to the TS-590.

It is NOT resonant on any band. It tunes well on ALL bands. It works DX like no other antenna I've had including some expensive tri-banders at 72 feet. Plus I don't have to wait for a rotator to stop on target.

I do have a TH6-DXX somewhere in the bushes behind the house, a nice tower to put it on, rotator, wires etc... Not worth the trouble to put it up. My "temporary" loop does it all.

My advice : Try the loop around your house, feed it with 450 ohm window line, assume that it wont be 200 ohm but use the 4:1 balun to get it down to within a reasonable tuning range for the TS-590.
Don't believe anything you read about it being a "cloud burner" or "not good for DX". I'm working on my 5th band DXCC and have over 300 countries confirmed on this antenna without a linear amp.

By the way, a tuner doesn't "work" any harder on a 10:1 mismatch than it does on a 2:1.

Hi Ken,

That IS encouraging!

Today my son and I installed a 40 meter doublet, it just fit on the front of the house.

Kind of a funny thing here. I told my son WE needed to do this, and the stress and steroids have me on edge, so just like when he was a kid three things would get us through this - do what you're told, when you're told and shut up! He countered by pouring me a toddy and saying "Piss me off too much and I'm outta this!" LOL! We met somewhere in the middle...

It's a 40 meter doublet constructed with #10 thhn stranded copper (overkill, but I had it), fence post electric fence insulators, a Ladder Loc center insulator and about 35' of 450 ladder line. The whole thing is only about 12-15' off the ground, under the house eaves, centered on the eave to stay away from the metal gutters and flashing as much as possible.

I don't have a standalone balun, so I have to use the one in the Dentron Super Tuner. I beleive it's a 4:1 voltage balun.

Unfortunately the balun can't be used separate from the tuner, so the tuner is always part of the equation, and I can get a 1:1 on 40 meters, but that resonance doesn't carry through well enough to allow the Kenwood to auto tune the harmonics like it does on the 10 meter dipole, so for now I'm stuck manually tuning it for each band change. I can deal with that as writing down the settings is close enough, once I dial in the Kenwood's tuner touches up. I don't like doing that though as the Kenwood writes that data to nvram and high use could eventually wear it out (probably not though).

So, I'm thinking a stand alone balun is what's needed, and it seems current rather than voltage baluns are suggested these days. Hopefully a stand alone would allow the Kenwood's tuner to work.

I'm not up on all the antenna theory and my vision issues are hindering study. Basically with the 450 ladder line, we're seeing 450 ohms on an equal length radiator antenna such as a dipole? If so, then a 9:1 balun would give the 50 ohms, but are hard to find pre-made and I'm not up to making one. I see Balun Designs has a 6:1 current balun, as well as the 4:1 baluns. 6:1 would step down to 75 ohm. The Kenwood's range is 16 to 150 ohms, so maybe a 6:1 would give it a little more range since it's more in the middle?

I may have to run the loop around the house now just to see if it works!

THANKS for your input, please let me know what you think about the 6:1 balun, I'd like to get one ordered soon.

Steve,

I wouldn't use any of those baluns. Why? Well, first of all, you don't know what you need. Without measuring the resistive and reactive components of the antenna for the bands of interest, you have no idea what ratio balun is needed. Typically, no single ratio will be correct for ALL of the bands of interest. Any given ratio might be good for one band, too high for others, and yet too low for some. Too, current baluns are generally preferred over voltage baluns for most applications. You could do some research and find out what some free space analysis or actual installations have revealed so that you have a good starting point for what might be needed. Then again, you could just believe what the ads say for the various baluns; makes life a lot simpler, it's not correct, but it's simpler and you can learn by experience why the ads might be misleading.

As a side note, there is likely to be significant loss in the balun. A balun is basically designed to convert a balanced line to an unbalanced line, or vice versa. It is NOT well suited for doing this transformation when reactive components are present in the load, your antenna. And you will have inductive or reactive components present in your antenna on the various bands. The best place for the balun is between the transmitter and the tuner, not between the tuner and the antenna. Yes, most tuners do the wrong thing, and thus, most tuners have higher losses and a variety of other issues unless you hit it lucky.

To simplify things, it is better to use a tuner designed for balanced feedline. See Richard Measures' articles about balanced tuners, get a Johnson Viking Matchbox, a Palstar BT-1500A, or build a suitable tuner with the balun at the input, not the output. Of course none of these tuners, or any tuner for that matter, will be set and forget across all bands since the resistive and/or the reactive components of the load will vary thus the compensating components of the antenna tuner network will need to be adjusted. You might be able to violate what theory says in this instance and find out that the tuner is dissipating more energy than the antenna is radiating; depending on SWR readings alone can easily take you down that path.

Finally, if you ever do get to try a horizontal loop, you might find that it reduces noise pickup. At my QTH, my horizontal loop reduced noise pickup by 1-2 s-units compared to a 1/4 wave vertical.

73,

Evan, K9SQG

Steve , I believe EVAN has given you sage sound advice for feeding your antenna.
In the tween time you might try a simple choke coil balun, known as an UGLY Balun,
between the 450 line and your Kenwood.
Just wrap 20 feet of RG8 type or RG8X on a 4 to 6 inch form and secure it.
I use plastic drain pipe for mine. then a short coax from balun to transceiver.
I have fed 450 and 300 ohm line this way and my transceiver tunes it well 40 to 10 meters on a 66 foot dipole.
If not satisfied then you can order a different balun.

Dr. Don HC4/W4BWS

One additional note. Your Kenwood tuner may not have enough tuning range to handle more than a 3:1 to 4:1 SWR.
This will necessitate using an external tuner. Most internal tuners are designed to allow a resonant dipole mid band to be used at higher or lower band limits- except maybe 80 meters.
So while it is desirable to have the internal tuner working, it often is not possible with a non-resonant antenna like using a 40 meter dipole on other bands.
Thus an external tuner is usually necessary.

Hi Don,

The Kenwood's manual says it will handle SWRs of 10:1 or less, and the messages here tend to show the 590 tuner is pretty robust. One never knows though, as mfgs frequently embellish and there are soooo many variables here. I'm waaay too low to the ground, waaay too close to a structure, etc.. I think the best thing is to simply do the phsycial analysis with an analyzer, just takes the guessing and assumptions out.

It's interesting my 10 meter coax fed dipole matched on 20 meter with the Dentron will allow the internal tuner to do 20 through 10 with just the upper half of 10 dropping off, but the ladder line fed doublet won't.

The reason I did the ladder line fed doublet was because it was my understanding that it was a type of antenna that allowed multi-band usage on the harmonics.

A club member in town has a fancy dancy analyzer, I'll give him a call.

Along these lines, I'm not adverse to buying an analyzer though once my antenna is set up I doubt I'll be playing much more, my vision just won't allow it. The SARK 100 Mini60s look capable and affordable from the Chinese vendors on fleaBay, but reviews on them are few and far between on the net, anyone have/use one? I'd love one of the Aussie Kit analyzers, but I'm not up to kit building these days adn they aren't offered assembled. The MJFs are 300 bucks for a good one, just too high.

Thanks!

Steve

My Buddy's analyzer is an MFJ and it won't do ladder line without a balun attachment, however he has a spare 4:1 current balun so I think over the weekend we'll just toss it on the shack end of the ladder line and see if the Kenwood is happy or not. If it is I think I'll run a wire around the house to make a loop and see what happens, if that doesn't work I think I'll cut it and then see if an 80 meter doublet will work. I'll post back after we play a bit.

I've never had a doublet/dipole outperform a horizontal loop antenna on any band. The 1-2 S-unit reduction in noise was an added benefit of the loop.

Yep, everything I've read Evan is very positive on the loop, which is why I was looking at putting four tilt up poles in the backyard for one, but then my vision issues crept up, so that's not in the immediate future.

I hope running a non-resonant loop around the house with the 4:1 current balun will allow the Kenwood auto tuner to do what I need. I'm sure the Dentron would work, but again, I'm newly low vision and manual setting up isn't so easy.

The nice thing about wire is it's relatively cheap and doesn't need much for construction skills, so even with my impaired vision I can get some hands on time with the help of my son.

I'm sure we will try the loop this weekend, I'll report back when we dol

http://www.eham.net/reviews/detail/4937

maybe that is for you???

If you make notes about tune settings in the manual tuner ... then you
should be very close

And fine-tuning could be done with that talking swr metre

Hey, that is pretty cool!

I gotta see what the talking module for the radio all does, I think it will do swr and power.

I played with the Kenwood and Dentron tonight, it seems the Kenwood has a decent tuner in it. If I get the Dentron purposely set to around a 3:! swr, which is the extreme right edge of the meter on the MFJ I'm using to set it up, and then hookup the Kenwood and have it tune it always does find a match. In fact giving each cap a tweak beyond so it's well above 3:! and it still seems to find a match, the Dentron can be set quite coarsely and the Kenwood is happy, so that gives hope that either a loop or doublet with it's own balun will work with the Kenwood tuner.

Playing with the Kenwood tonight...I continue to be impressed with it! 8-)

Just playing, this isn't exaclty loop related, but I think interesting none the less, so I hope I'm not boring the group.

It's easy enough to compare the 10 meter dipole to the doublet on 10 meter as I have two antenna hookups to the new rig so I can easy switch between the doublet/tuner and dipole and compare reception within seconds.
.
It's hard for me to see the little notches on the meter, but it appears the signal to noise ratio is greater on the dipole, it seems about double. Not that the dipole is pure noise, it's just twice as much noise as the doublet. I found a couple beacons and that held true, switching antennas basically doubled the signal strength coming from the beacons, so more wire DOES equal more signal!

4640. Low, non-resonant loop is UP!

OK, hot bright day, fat blind guy suffering steroid jitters on a ladder...nothing could possibly go wrong here, right?

RIGHT!

I ran a wire the rest of the way around the perimeter of the house and hooked it on to the end of the doublet to make a horizontal loop antenna.

It's working well, the Dentrpn can match it easily from 80 to 10 meter!

It's about half again as quiet as the doublet for background noise and a good gain for signals over the doublet.

I can't read the lcd meter on the Kenwood too well, it's got several scales though and one I can read fairly well. There's a 10 meter beacon I was playing with. On the dipole it was on 5, on the doublet it was on 10. When I got the ends tied together I came back in, the dipole is still at 5 but the loop is at 18! 8-)

Ran near the cable tv for a bit, but no interference issues.

I think it's a keeper!

The Dentron is matching it easily. When it's configured as a doublet the Dentron can match it, but some bands are touchy, it seems with the loop they're not nearly as touchy.

The Dentron has a 4:1 voltage balun in it, I'm hoping to get to play with a stand alone 4:! current balun this weekend, I really hope the Kenwood's tuner will be happy with a balun and will be able to tune the loop it's self.

The saga continues...and it's an absolute hoot, I LOVE this kinda stuff!

I usually monitor the KC0SWG repeater around 10 pm most nights, if you Echolink and want to try and hookup on HF give me a yell on the repeater sometimes....I'm starting on my Worked All States award though, so if we hookup on HF I'll need a QSL card! 8-)

Now you know hwy some guys say "if you ever tried a loop you will never use any other antenna again"

What counts most (in my view) is the low noise (or high signal to noise ratio)

And my findings her about matching ... a big loop can be used nearly on any frequency ... impedance is always in midrange (so easy to match with a tuner)

On fundamental frequency a dipole has low impedance and on next harmonic it has very high impedance .. a loop always is in mid impedance

Even between the resonance spots the impedance does not bounce skyhigh (like on a dipole on 2nd harmonic) ...

You sure found a keeper :-)

Steve,

For your particular installation, you home and shack are in the midst of the antenna. If you use a linear it might induce some RFI etc. Curious to see how you'll be using the antenna in the weeks ahead.

I think for the most part the fields inside the loop are reinforcing, not canceling. I think the field is most intense in the middle. Think what happens with an electromagnet or solenoid.

"I don't think there is any antenna modelling program that can make a in the loop pattern ya know?"

I believe NEC calculates the fields inside a loop. NEC does do near-fields too. It's just that most people don't bother to look at the near-field results; they only look at the far-field patterns.

Even EZNEC can generate near-field tables.

Andy

Hi Evan,

I don't think a linear or anything is in the immediate future. My vision issues were fast coming and probably permanent, so working and the occasional overtime for extras is probably a thing of the past. We're seriously just hoping to hold on to the house, so that's why no major antenna support structures are even being considered.

I'm sticking with what I have for now, a Kenwood TS-590SG and an old Icom IC-730 I was in the midst of refurbing when this all hit. I also have a Dentron Super Tuner and Dentron Jr tuner. But that is it, I was just returning to amateur radio after a 30 year hiatus (formerly KA0JXR, novice at 13 in 1978, Tech in 1979 and General at 15 in 1980, but I let it expire as I got older).

I plan on using the station for general qsoing, I'm hoping to play with PSK31 and weak signal propogation reporting if the program will play nice with the huge high contrast fonts my vision requires.

If things settle down for me and we stay here, then the antenna will be the first order of business for upgrade, till then, I'm stuck with low things that can mount to the structure of the house.

So far, no rfi problems on any band at full power...well, one...the touch lamp in our bedroom will turn on occasionally when transmitting, but a CB in the driveway will do that to it too, so we're getting a new lamp!

I have been keeping an eye on this topic.
I think this wire loop is indoors?
I'm on the 4th floor with severe antenna restrictions.
I use a standard mag loop with steel above and below me and have worked DX over 10,000 miles with 5 watts.
I can install a 20 x 20 foot square wire loop.
Will this work for me?
Any information is much appreciated
BOB AF2Q

Very true, I guess ya can run low power and use a field strength meter and walk around the house and look at the varying strengths.

Hi Bob,

My loop is installed on the outside of the house, my roof overhangs my house walls by a couple feet so it's installed under that overhang between the outside wall of the house and the metal rain gutter.

I can tune 80 meters and up with around 200' of wire, and it seems the more wire the better, so I'd think your 400' would definitely be usable.

As far as installing it inside, in/near a building, with steel above and below, etc. I'd say no one can give you an answer, there's just a LOT of variables there, if you can install it cheaply then I'd say just give it a try and then you'll know for sure, anything else is guessing and it's not even educated guessing as sooo much is in play.

I know, not a good answer, I had similar questions about my install and in the end simply ran the experiment to find out.

Take care, 73s,

Steve KA0NEB

Hi Steve,
The loop I am thinking about will be a total of 80 feet of wire.
I have worked as far as Texas with just a wire hanging out the window and never have a problem getting over the pond with a 3 foot mag loop.
Well,it's all about experimenting so I will see how it works.
I usually just work 40 and 20 meters.
73 es Tnx for responding

Hi Guys,

OK, the wheels are turning on how to get this up higher. I really don't want to do any major projects, but my condition can take months to heal to whatever state it's going to, and fortunately I've never abused sick time so I have almost a year's leave time before I either have to get back to work or go on disability. Even at that, we may get something figured to keep the house, so I'm cautiously exploring options. Oh, I have an old truck I won't be using any more that the neighbor is interested in, so I may sell it to fund the antenna project.

First is economics, second is location and of course zoning and stuff comes into play.

Economics, as cheap as possible of course! That rules out four towers but it also rules out cheap iffy pfc and expensive fiberglass too. It appears that Rohn makes a 35' telescoping mast that's UPS shippable, about $150 each. $600, ouch, but then again...not really, figure the cost over the time of use... There are other makers, for a few bucks less, but I think Rohn has a good reputation and product.

Location may play into zoning a bit. The rules on antennas, towers, masts and even flag poles are kind of murky here. Basically an antenna on a house can't exceed 60' off the ground, but a tripod and guys to the roof suffice, no real size of roof is required. Kind of interesting. Towers have rules, setbacks, etc.. Probably not an option. A mast doesn't really have rules though, as long as it's securely attached to the structure, which again could be a tripod, guys, etc, OR set in the ground and bolted to the side of the structure. A tower usually consists of more than one element, i.e. it is triangular or square where as a mast is usually one element, i.e. a pipe or collapsable pipe. A mast that stands alone or is guyed is murky area, the Inpsector thought for guidance the flag pole criteria may apply.

Soooo, I think four Rohn 35' telescoping masts attached to each corner of the house would be fine.

That leaves me with the same size loop. I'll know if that's what I want to do soon when I see if the stand alone balun lets the Kenwood's tuner work standalone.

My thought is one of those on each corner, so attached to the house at around 12'. Then I'm thinking just two guys to a corner coming off at right angles around 25' as the antenna wire will connect the four corners of the rectangle and help spread load?

This keeps the antenna over the house though, so the house and shack are within the antenna. It's not an issue now, so probably not one later either.

I can move into the back yard, but then I get into masts that aren't connected to a structure issues. I'm sure it's doable though. The only issue there is that the power feed to the house would drop through the middle of the rectangle, no way around it.

35' enough? Does it have to be all 35'? Two 35' corners sloping down to 15' corners do ok?

Just kicking around ideas. I've even considered maybe a Windom or something, but fitting an 80 meter in would be hard and though I can tune the 40 meter doublet to 80, I dunno how a Windom would do.

Any thoughts, comments, etc.. I'm not thrilled with doing a big project, but this isn't that big or expensive and I think would increase the enjoyment a lot, antennas are the best bang for the buck!

Bob,

You are comparing different kinds of loops here.
They work completely different.

Your mag loop is probably the best antenna you are going to find for indoor use in most households, unless you live in the country in a wooden house and have very little consumer products inside your house.

The SkyLoop is generally one wavelength or longer on the lowest frequency you plan to use it, and works on the electrical component of the signal. The Mag Loop, if built properly, does not. It works on the magnetic component of the signal.

Noise generated inside the house will be picked up by a 20□ by 20□ wire loop, but not nearly as much so by a magnetic loop.
It might be that someone far away will hear you on the 20x20 loop but you probably won□t be able to hear them.

Having said that, be aware that all Mag Loop antennas were NOT created equal. There night and day differences between really good ones and most of the loops most people are using. Trouble is, the really good ones cost big time bucks!

Personally I think EZ-UP and Rohn are coming out of same factory after an EZ40 I bought had the (wrong) spec sticker for an H40 on it. I have both an EZ40 and an H50. The clamps are different.

How are these poles "attached to each corner of the house" going to go up thru the roof (at the eave)? Obviously not. Is the roof a gable roof or a hip roof? I'm suspecting a hip. So are you going to buy brackets (2 or 3 per corner) to offset the poles out from under the eaves. Like these http://www.dxengineering.com/parts/roh-wm18s ? @ $38? You're up over a couple hundred per corner aren't you?

I also have my doubts about two of these brackets holding a 35' push up pole. Maybe 10' of ridged EMT.
<http://www.dxengineering.com/parts/roh-wm18s>
Now that we've worked up to push-up poles...

Do you not have ANY trees above the eave height? Leave one leg under the eaves and expand it up and out thru a couple trees. This would enlarge the loop and bring three legs of it up. Even if you had to hire someone to put some attachment loops up in 3 trees I think it'd be way cheaper than the $800+ u r looking at. High school kids are looking for money about now. I think your total expense with a 3 tree solution is under $100 including the monkey hire. Save the $750 for future house payments.

I also saw an article where a guy used concrete filled buckets or tires to hold 20' galvanized pipe poles up for a loop. He just attached the loop and walked them up and tied the poles off in the opposite direction with Dacron rope. Very adjustable and certainly a quarter of the push-up solution cost at about $30 per corner.

The sum of the measures of the three exterior angles (one for each
vertex) of any triangle is 360 degrees.^[note 2]
<http://en.wikipedia.org/wiki/Triangle#cite_note-7>

Geometry must have changed since I went to school.
A triangle has 180 degrees total.

Dr. Don HC4/W4BWS

4673. Re: AW: AW: AW: [SkyWires] Low, non-resonant loop is UP!

Yahoo group: SkyWires
Date: 2015-06-11 00:19:17 UTC
From: Skip Guenter
Topic: 4640 Message: 4673

It has 180 of total INTERIOR angles. If you read again you will see we specifically were talking about EXTERIOR angles. Albeit totally irrelevant to the original topic.

The sum of the measures of the interior angles of a triangle <http://en.wikipedia.org/wiki/Sum_of_angles_of_a_triangle> in Euclidean space <http://en.wikipedia.org/wiki/Euclidean_space> is always 180 degrees.^[5] <http://en.wikipedia.org/wiki/Triangle#cite_note-6> This fact is equivalent to Euclid's parallel postulate <http://en.wikipedia.org/wiki/Parallel_postulate>. This allows determination of the measure of the third angle of any triangle given the measure of two angles. An /exterior angle <http://en.wikipedia.org/wiki/Exterior_angle>/ of a triangle is an angle that is a linear pair (and hence supplementary <http://en.wikipedia.org/wiki/Supplementary_angle>) to an interior angle. The measure of an exterior angle of a triangle is equal to the sum of the measures of the two interior angles that are not adjacent to it; this is the exterior angle theorem <http://en.wikipedia.org/wiki/Exterior_angle_theorem>. The sum of the measures of the three exterior angles (one for each vertex) of any triangle is 360 degrees.^[note 2] <http://en.wikipedia.org/wiki/Triangle#cite_note-7>

And Sigi, Yes 900 for ALL exterior angles.

4674. Re: AW: AW: AW: [SkyWires] Low, non-resonant loop is UP!

Yahoo group: SkyWires
Date: 2015-06-11 00:15:23 UTC
From: Don Sanders
Topic: 4640 Message: 4674

From Wikipedia
Basic facts
<http://en.wikipedia.org/wiki/File:Remint3.svg>
<http://en.wikipedia.org/wiki/File:Remint3.svg>
A triangle, showing exterior angle d.

Triangles are assumed to be two-dimensional
<http://en.wikipedia.org/wiki/Dimension> plane figures
<http://en.wikipedia.org/wiki/Plane_figure>, unless the context provides
otherwise (see Non-planar triangles
<http://en.wikipedia.org/wiki/Triangle#Non-planar_triangles>, below). In
rigorous treatments, a triangle is therefore called a *2-simplex
<http://en.wikipedia.org/wiki/Simplex>* (see also Polytope
<http://en.wikipedia.org/wiki/Polytope>). Elementary facts about triangles
were presented byEuclid <http://en.wikipedia.org/wiki/Euclid> in books 1–4
of his *Elements <http://en.wikipedia.org/wiki/Euclid%27s_Elements>*,
around 300 BC.
<http://en.wikipedia.org/wiki/File:Triangle_sommeangles.svg>
<http://en.wikipedia.org/wiki/File:Triangle_sommeangles.svg>
The measures of the interior angles of the triangle always add up to 180
degrees (same color to point out they are equal).

*The sum of the measures of the interior angles of a triangle
<http://en.wikipedia.org/wiki/Sum_of_angles_of_a_triangle> in Euclidean
space <http://en.wikipedia.org/wiki/Euclidean_space> is always 180 degrees*.
[5] <http://en.wikipedia.org/wiki/Triangle#cite_note-6> This fact is
equivalent to Euclid's parallel postulate
<http://en.wikipedia.org/wiki/Parallel_postulate>. This allows
determination of the measure of the third angle of any triangle given the
measure of two angles. An *exterior angle
<http://en.wikipedia.org/wiki/Exterior_angle>* of a triangle is an angle
that is a linear pair (and hence supplementary
<http://en.wikipedia.org/wiki/Supplementary_angle>) to an interior angle.
The measure of an exterior angle of a triangle is equal to the sum of the
measures of the two interior angles that are not adjacent to it; this is
the exterior angle theorem
<http://en.wikipedia.org/wiki/Exterior_angle_theorem>. The sum of the
measures of the three exterior angles (one for each vertex) of any triangle
is 360 degrees.[note 2] <http://en.wikipedia.org/wiki/Triangle#cite_note-7>

"The exterior angles of a triangle total 360."

Um, when I was growing up, in math what you are referring to were were called "supplementary angles".

Basically, the amount that each angle must deviate from continuing on straight (= a 180 degree "angle") adds up to 360 degrees, for any closed polygon.

And for a triangle, it happens that the sum of the interior angles themselves, adds up to 180.

Ain't geometry fun?

I don't recall studying anything called "exterior angles" in math. Maybe that's because it has multiple, conflicting definitions! One definition is that it is the entire sweep around the outside of the angle. So for a 60 degree angle, the exterior angle (by that definition) is 300 degrees, and three of them adds up to 900 degrees as Sigi rightly points out. See, for example, this page from Wolfram's Mathematica:
http://mathworld.wolfram.com/ExteriorAngle.html

Now back to your regularly scheduled program.

Hi Skip,

I'll look at EZ-UP, thanks.

Talking to the Building Inspector the suggestion was a piece of pipe cemented in the ground and the mast set over it. Easy enough, I have relatives who run a welding shop and a neighbor who works for the concrete company, so dig a hole, grab a piece of scrap pipe from the shop, stick the pipe in the hole and when they have a skosh of concrete left over we'll set it. Then the suggestioh was coming out from under the eaves with something attached to the trusses. He said wood, steel, etc. would work. Frankly he said those flimsy brackets would be fine. Again, relatives run a welding shop and even have one who's a carpenter, so I think this isn't too big of a deal. The Inspector gave the impresson they weren't too interested in masts and no one really asks before putting them up (and there's been a lot going up as since digital tv has came on all the networks and several lesser stations on the sub channels are now available, before digital we got CBS, ABC and PBS and that was it, now I think he said we have 18 total channels available, so people ARE cutting the cord an putting up antennas again)

There are zero trees on my property - our neighborhood was mostly maple trees and a tornado a couple years ago damaged the back two and carpenter ants tore the crap out of the two in front (carpenter ants love maple trees, especially damaged ones, and the neighborhood was full of damaged ones after the tornado...if you have to fight carpenter ants, use a spray called Termidor - it WILL kill them!). So no matter what antenna I choose, I will have to erect a support for it, no way around that.

I don't think the bucketed concrete poles would pass muster, though he did say he would check into stand alone masts vs towers for me. He also mentioned that flag poles are relatively unregulated, so hang a flag with the wire?

I had discussed tilt up masts made from two pieces of sch40 plumbing pipe slid inside each other with him earlier before my eye issues and he was receptive to them, but 21' lengths of sch40 aren't cheap either.

I may just end up with two supports for half the cost and then a Windom, doublet or something similar, though the performance of the loop vs my doublet makes me think the loop would be worth the extra cost. Again, just gotta amatorize the cost over the expected years of use. You can't figure the cost of poles, wire, etc. separately, it's all a system, so just figure a system cost...

I've had great luck with fiberglass. I've used Hot-Sticks when there is a need to extend/retract repeatedly, with lengths/heights up to 40 ft. Also, I've had great success with telescoping sections that I bought from Allen at Max-Gain Systems; great prices, great service, great guy; these are the ones I currently use by anchoring them to some trees, although they could attach to a house or whatever.

The Rohn 9h50, 34' extended, runs $154 delivered from DX Engineering. I think that's pretty hard to beat. Plus, I'd think galvanized steel would outlast the fiberglass and flex less in service.

Still looking at options, this doesn't have to be sorted in a day...

When speaking of angles between wires, we ALWAYS refer to their inside angle, not there outside angle. All text books, all articles and all other antenna groups use inside angle when referring to antennas.

A dipole with its legs bent down is referred to as an Inverted-V and it is said not to use an angle less than 90 degrees. Obviously it is referring to the lower angle (between the wires).

If we then bend the wires back up to a dipole position, and continue upwards another 20 degrees on each side, we change the name of the antenna to Vee instead of Inverted Vee and again speak of its inside angle of 140 degrees. We never refer to the outside angle.

60 degrees Inside EQUALS 120 degrees outside

This entire silly argument was only about semantics and doesn’t really help anyone trying to understand how to build loops.

I joined this group just yesterday, expecting to learn something about loop antennas and possibly share my experience with them.

So far I have only been reminded of my 8th grade math class. (hi)

Steve hit on one important point: Good masts are expensive. But so are good antennas. And the loop is an outstanding antenna.

IMO, 20 ft. is too low if you want to also work 80m. It’s OK for 40 and above.
And of course if all you can do is 20 ft., so be it; do it, even on 80.

If you have the space to run back-guy ropes, then you can get away with thinner material, which saves a lot of money.
If the mast must be self-supporting, then it’s gonna cost a bit to get 3 or 4 of them up.

The cheapest way I have found unfortunately won’t work for everybody.
But if you live close to an area where there are trees, using wooden poles makes good sense.
A wooden pole makes a great antenna support because it is non-metalic, but how do we erect it and what kind of base do we use.

Base: the cleverest solution I have seen was using steel I-beams. It would be better to use galvanized but you can also paint them several times. Simply Cement an I-beam into the earth about 2 to 3 ft. (depending on how solid the earth is at your QTH) with about 4' projecting above ground.

The wooden pole will be strapped inside the "I".
The beauty is, you can also strap a shorter, heavier pole such as a 10' steel pipe, and use that a a gin pole to pull the 30 or 40 ft. wooden mast up.

It looks like this from the top:
Gin-Pole-I-Wood-Pole
_____OIO_____

Then buy a case of beer and invite the local ham club over.
It takes about 10 minutes to explain the plan, then about 10 minutes per pole.
THEN you drink the beer. (hi)

Of course this also works for pulling metal poles up.
Don't forget to mount a stainless steel pulley and rope on each of the 4 masts before erecting them.

Now the question is, how do you remove the rope from the wooden mast used for pulling it up.
Answer: You don't. You leave it attached. When you remove the gin pole, the pull-up rope slips out of the gin pole's pulley and hangs down. Secure excess to the Wooden mast.

Well, a fiberglass equivalent might be a tad bit cheaper. By sizing the fiberglass sections properly, you can indeed establish some flex which helps to save the mounting mechanism under dire circumstances. My poles have been up almost 20 years and show no sign of deterioration. How long it takes a Rohn mast to rust, not sure, periodic maintenance/painting (even if galvanized), not sure about that. To each their own...

Hi Evan,

Remember I'm vision impaired, so I didn't dig all the way through every fiberglass pole web site, but I hit the popular ones and it seemed they all were the same price, or more commonly higher, than the Rohn and that price didn't include shipping. Most were not as large of a starting or ending diameter as the Rohn either. I'm sure fiberglass does work, but I'm pretty sure galvanized steel will too and I'm just old fashioned and more comfortable with it.

Hi Rick & All,

Yeah, I'm viewing it all as antenna cost and if you figure the cost per band, per year of use, it'll amatorize.

I'm still playing with my too low loop and won't really know much until I get the stand alone balun to play with, but a few questions still lurk.

Height still is a question, what is the minimum workable? I think I do want 80 meter as I can tune to it at my current wire length and I was surprised it was quite active later in the evening, seemed like friendly groups, the one group that tolerated my weak intrusion were very friendly and patient pulling me out of the background noise. 34' is the highest UPS shippable mast I can find, but the tilt up masts from sch 40 pipe aren't off the table either.

Wooden poles - are you talking simply trees with the branches removed, or pressure treated utility poles? What diameter?

Shape - my current loop is a rectangle about 65' on the long edges and 30' on the short edges. Square better?

Feedpoint - I've read the feedpoint can affect the directivity? I'm near Lincoln, Nebraska so I'd think I'd prefer to orientate towards Europe?

Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?

I would never sell my truck for a simple wire antenna installation

I would hang my wire wherever I have room

In a tree (even if on neighbours ground! ... you can use a longer rope from there) ... some fibre glass camouflage net poles (they are CHEAP!!!)

These poles can be bought for a few bucks (maybe 20-30 bucks for a 25-30 feet pole) ... no expensive rohns needed for just a wire antenna

I would install a wire antenna (either a big loop or a ladderline fed doublet ... or both ...

And use the saved money to install a small tower (tripod or similar) on the roof for a small beam for the higher bands ... topping that with a vhf and uhf beam and a vhf/uhf vertical

... add a vertical for the lowbands in the backyard ... and then youre all set

I am poor and retired so I don't have a lot to spend here, I feel your pain. (I think that's what Bill said). I cant afford to buy so I build.
Here is a sketch of my 30ft tilt over.
http://i1102.photobucket.com/albums/g453/KD0ZZ/Tilt2.jpg
Note the picture of the 30ft tile has a smaller pipe in it because it was being used as a 20ft tilt testing a 2M antenna. It held up a beam and rotor until I built the 40ft tilt .
Click a few pictures to the left and you will see my 40ft tilt and it is simpler to make, just a couple of holes to drill.

Steve

The trees I’m speaking of are just trees with bark and limbs removed.
They may be painted or oiled but they are not pressure treated utility poles.

I live in Bavaria (even though it is near Frankfurt) and here we have a tradition of raising a May Tree (Maibaum) on the first of May, each year. Every city, town or village does that. We can buy trees untreated or already painted in white and blue stripes.

Here is what such an event looks like (hope the link works):
http://www.sueddeutsche.de/muenchen/pflicht-fuer-bewohner-der-stadt-was-echte-muenchner-im-fruehling-machen-1.1309161-6

I understand you are vision impaired but I don't know to what extent.
If you are unable to see the picture, perhaps someone can describe it to you.

Obviously your trees would be a wee bit shorter (hi).
As you can tell by the picture, the boys have their act together.
They put these up by hand; pure manpower, using only sticks to push it up.

Lots of people put these in their yard, but of course mostly only about 30 ft. high.

Now to the ELECTRICAL PART:

If you wish to feed your loop with coax, it is probably better to have it very close to resonance on either 80m or 40m.
This means about 275 ft. or 137 ft. This keeps the impedance on harmonic bands close to 100 to 150 Ohms. You can then use a 2.5:1 or 4:1 balun to match them.

If you are feeding with Openwire feedline and have a good antenna tuner, then having it resonant on the ham band is not so important.

RADIATION PATTERN:

I have only built and used square loops. I have never made mine in a triangle or some other shape.

>>>On the fundamental, you get a fairly round 360 degrees radiation pattern, and covering medium to high angle radiation angles.

>>>On the second harmonic (i.e. 40m for an 80m resonant full wave loop), you get 4 major lobes, one off of each corner. Its high angle radiation is reduced a lot but still fairly good in practice. There is also good radiation off the sides, though not so strong as off of the 4 corners. These are fairly wide lobes. I find a 2 wl long loop to be one of the best omni-directional antennas going.

>>>On the 4th harmonic and higher, as well as the 3rd harmonic for a 40m loop, the major lobes are horizontally a bit narrower and vertically, radiate much lower, which is

outstanding for DX. HERE IN EUROPE THIS IS BENEFICIAL!

If I build my 80m loop with its wires running exactly North-South and East-West, then on the higher bands, I get:
>>>a NW lobe beaming Stateside
>>>a NE lobe beaming JA and Northern Pacific
>>>a SW lob beaming Long Path to VK/ZL
>>>a SE lobe beaming the Middle East

That’s about as good as it gets, short of having a rotary beam!

Of course any object in the vicinity of the antenna might affect its radiation pattern.

Since I have no experience with a triangle loop, I won't bother you with my speculation on how it might work. I prefer to talk on antennas with which I have a lot of experience.

If I were you and had the space, I would try a full wl on 80m. Something like 275 ft. Everett, N8CNP just put one up and I put up the details of his loop on my web site.

Hi Rick & All,

Yeah, I'm viewing it all as antenna cost and if you figure the cost per band, per year of use, it'll amatorize.

I'm still playing with my too low loop and won't really know much until I get the stand alone balun to play with, but a few questions still lurk.

Height still is a question, what is the minimum workable? I think I do want 80 meter as I can tune to it at my current wire length and I was surprised it was quite active later in the evening, seemed like friendly groups, the one group that tolerated my weak intrusion were very friendly and patient pulling me out of the background noise. 34' is the highest UPS shippable mast I can find, but the tilt up masts from sch 40 pipe aren't off the table either.

Wooden poles - are you talking simply trees with the branches removed, or pressure treated utility poles? What diameter?

Shape - my current loop is a rectangle about 65' on the long edges and 30' on the short edges. Square better?

Feedpoint - I've read the feedpoint can affect the directivity? I'm near Lincoln, Nebraska so I'd think I'd prefer to orientate towards Europe?

Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a

tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?

Hi Evan,

Remember I'm vision impaired, so I didn't dig all the way through every fiberglass pole web site, but I hit the popular ones and it seemed they all were the same price, or more commonly higher, than the Rohn and that price didn't include shipping. Most were not as large of a starting or ending diameter as the Rohn either. I'm sure fiberglass does work, but I'm pretty sure galvanized steel will too and I'm just old fashioned and more comfortable with it.

Hi Sigi,

The truck is truly spare. Before all of this hit my main hobbies were high power model rocketry and presenting public fireworks displays (I did them labor free, the community just had to buy the fireworks, my crew and I provided the equipment and manpower). This truck was used to haul the trailer and equipment. I can no longer do that though and one of my crew members has taken them over and he as a truck for the job, so this one is truly spare.

I have a nighbor who does a lawn service in his spare time and wants an older truck that he won't mind if it gets a scratch or two on it, so it's kind of a good match for us to make a deal.

It's truly a net gain for me, both in the sale and not paying tags and insurance on it, so I'm not hocking my stuff just radio play, it's just truly spare and though the future is uncertain, I do want to remain in radio, a man does need a hobby, so converting it from something I'm not using to something I would is something I'm comfortable with.

There's no neighbor trees either! Again, we had a tornado skip over the neighborhood a few years ago and this is an older neighborhood, it was full of elm trees which got killed off by disease, and maple trees which took over. The maples didn't make the storm damage well and the damaged ones left got attacked by carpenter ants, they were terrible in the couple years following the storm and tore the crap out of any tree left it seemed (the tree will look sound, but the inside will be completelyhollow!). We're recovering now, many have replanted trees but they're still small. The carpenter ants are gone - a chemical called Termidor, which is actually for termites, is carpenter ant death and it's cleaned up the problem (if you buy it and use it yourself, don't expect a fast kill, it's a slow acting one that kills the queen and colony).

The only thing sticking up in the air around here are the off limits utility poles!

Rick,

Thank you VERY much for the tuner sheet and the good info.

I'm about to string up a 75m/80m loop (insulated 14awg stranded copper) and side or corner feed it with 450 ohm window line directly (thru the wall) into the back of my Palstar AT2K (old one with a 4:1 current balun in it).

It's PRIMARY function will be to replace the 75m coil loaded section of my Alpha-Delta DX-CC dipole for use on 3.9MHz SSB. However I occasionally run, via tuner, down on the digi portion of the band ~3.58MHz.

It would also be a REAL bonus if the loop was also good on 7.19Mhz (my primary band segment) to supplement the dipole.

The loop will have a high corner (possible feed point) of around 10.5m with it slopping away to ~7.2m at the other 3 corners and will be slightly rectangular with it longer E-W than N-S. I could also feed it at 7.4m high on the east leg that's running N to S due to it's close proximity to an unused pulley I have in a tree there.

Finally to the questions. Should I cut this for 3.58MHz or 3.9Mhz considering it's intended mission? Anything to consider to increase odds of it out performing my dipole on 7.19Mhz? Any other suggestions?

Tschuess, Skip

Hi Rich,

Yes, that's exactly what I was looking at before all of this hit, and it still may be where I end up, I'm just looking at options right now.

I really think a tilt up like this is the least expensive option and the most convenient since no guys needed.

I need to keep in mind the future though and if we don't stay here then the tilt up isn't very portable and I may be forced to spend money over on something that is portable.

No easy choice here, but an undefinite future makes choices hard.

This has my vote for permanent installs though!

Hi Rick,

I can see big things, but I have grey streaks in my vision and poor contrast, the light from a 100 watt light bulb probably looks like a 40 to me. Picture dim with not enough pixels. Still, I can blow most pics up, invert colors and stuff. I did get the gist of your pic, thanks!

I'm using ladder line currently and see no reason to not continue with it, it seems to be working fine.

I don't think I could stick a tall tree stump in the yard, I'm pretty sure someone would say something! LOL!

I'll digest the electrical facts here in a bit, thank you!

The first (smaller) tilt up is portable. At my first installation I knew we would move in a few years so it is mounted on threaded rods, ready to move, cut off rods and install a little sod.

When i retired I bought the land in a rural county, no rules or regulations, do what ever I want. Installed a lot of power, 400 amp service transformer with 400 amp fused disconnect, 200 amp wire to house and 200 to shop .
The larger tilt is into ground and someone else's problem when I die. It now supports a hex beam and feed point for a 160 delta loop used on 160/80/40

I like those tilt ups, I really do, just looks like the best bang for the buck. Removal wouldn't be that difficult if one gave thought to the base base when creating it so it could be easily lifted off and the rest left and buried.

The only real issue is the length of the pole it's self, I wonder if coupling smaller lengths would be strong enough?

Hello Skip,

The 80m loop sounds good. No, it sounds GREAT.

When running openwire, it makes absolutely no difference whether you tune it for 3.6 or 3.9 MHz.
The QSO partner at the other end will notice about as much as you and I notice when a sack of rice falls over in China.

Performance on 40m is going to be outstanding. As I said earlier, a 2 wl loop is one of my favorite antennas overall.

With Coax it would be a different story. Here I would always choose a resonate frequency 3.6 MHz or even lower (i.e. 3.55 MHz) so that the harmonics fall within the upper ham bands. With 3.9 MHz, all of its harmonics are outside of the higher bands. The SWR may be a bit high on 75m, so use a tuner.

The AT2K is an outstanding tuner, but I recommend not using its built-in balun.
In later models, Palstar removed the balun and went to external baluns.
They offer both a 1:1 and 4:1 external balun but the 1:1 is the better choice.

The very best kind of balun to ALWAYS use when feeding openwire fed antennas is a 1:1 Guanella balun.
I know most people believe a 4:1 is better but it’s not. That is a myth, nothing more.
For the following two reasons:

>1. The number one most important job of the balun is to keep common mode current out of the matchbox. With a perfect 1:1 SWR, the common mode impedance (CMI) of a 1:1 Guanella and a 4:1 Guanella Balun are close to being the same. As the SWR rises, the CMI of the 4:1 quickly goes to hell in a hand basket, whereas the 1:1 marches on like a super trooper, maintaining high CMI.

>2. Except for 160m, your AT2K has less than 10% loss with impedances from 12.5 Ohms up to over 1600 Ohms. There is zero benefit in using a 4:1 transformer in front of it to drop the impedance.

As for "which external balun", well I wind my own but if I were to buy one, the only one I would buy is the Balun Designs Model 1171. It's not cheap, but neither was the Palstar or any other quality product.
See: http://www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/?page_context=category&faceted_search=0

It is important for people to realize that:

>1. there are many different kinds of baluns because we have so many different applications for them.

>2. There is an awful lot of crap being offered for sale and many times the people selling them have no clue what they are talking about. So do your own due dilligance.

>3. One of the best ways to shoot yourself in the foot is to skimp on the balun. Not only can it end up being lossy and eating half your power, it can also be the cause of many unwanted side effects, such as TVI, hot mics, etc., simply because it is not doing the job it was supposed to do - even though it cost a lot of money. Sometimes that's because the product itself is crap, but often it is a good product but not the right one for the job at hand.

With a good external balun Skip, you're going to be very pleased with your loop.

Subject: Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

Thank you VERY much for the tuner sheet and the good info.

I'm about to string up a 75m/80m loop (insulated 14awg stranded copper) and side or corner feed it with 450 ohm window line directly (thru the wall) into the back of my Palstar AT2K (old one with a 4:1 current balun in it).

It's PRIMARY function will be to replace the 75m coil loaded section of my Alpha-Delta DX-CC dipole for use on 3.9MHz SSB. However I occasionally run, via tuner, down on the digi portion of the band ~3.58MHz.

It would also be a REAL bonus if the loop was also good on 7.19Mhz (my primary band segment) to supplement the dipole.

The loop will have a high corner (possible feed point) of around 10.5m with it slopping away to ~7.2m at the other 3 corners and will be slightly rectangular with it longer E-W than N-S. I could also feed it at 7.4m high on the east leg that's running N to S due to it's close proximity to an unused pulley I have in a tree there.

Finally to the questions. Should I cut this for 3.58MHz or 3.9Mhz considering it's intended mission? Anything to consider to increase odds of it out performing my dipole on 7.19Mhz? Any other suggestions?

The trees I’m speaking of are just trees with bark and limbs removed.
They may be painted or oiled but they are not pressure treated utility poles.

I live in Bavaria (even though it is near Frankfurt) and here we have a tradition of raising a May Tree (Maibaum) on the first of May, each year. Every city, town or village does that. We can buy trees untreated or already painted in white and blue stripes.

Here is what such an event looks like (hope the link works):
http://www.sueddeutsche.de/muenchen/pflicht-fuer-bewohner-der-stadt-was-echte-muenchner-im-fruehling-machen-1.1309161-6

I understand you are vision impaired but I don't know to what extent.
If you are unable to see the picture, perhaps someone can describe it to you.

Obviously your trees would be a wee bit shorter (hi).
As you can tell by the picture, the boys have their act together.
They put these up by hand; pure manpower, using only sticks to push it up.

Lots of people put these in their yard, but of course mostly only about 30 ft. high.

Now to the ELECTRICAL PART:

If you wish to feed your loop with coax, it is probably better to have it very close to resonance on either 80m or 40m.
This means about 275 ft. or 137 ft. This keeps the impedance on harmonic bands close to 100 to 150 Ohms. You can then use a 2.5:1 or 4:1 balun to match them.

If you are feeding with Openwire feedline and have a good antenna tuner, then having it resonant on the ham band is not so important.

RADIATION PATTERN:

I have only built and used square loops. I have never made mine in a triangle or some other shape.

>>>On the fundamental, you get a fairly round 360 degrees radiation pattern, and covering medium to high angle radiation angles.

>>>On the second harmonic (i.e. 40m for an 80m resonant full wave loop), you get 4 major lobes, one off of each corner. Its high angle radiation is reduced a lot but still fairly good in practice. There is also good radiation off the sides, though not so strong as off of the 4 corners. These are fairly wide lobes. I find a 2 wl long loop to be one of the best omni-directional antennas going.

>>>On the 4th harmonic and higher, as well as the 3rd harmonic for a 40m loop, the major lobes are horizontally a bit narrower and vertically, radiate much lower, which is outstanding for DX. HERE IN EUROPE THIS IS BENEFICIAL!

If I build my 80m loop with its wires running exactly North-South and East-West, then on the higher bands, I get:
>>>a NW lobe beaming Stateside
>>>a NE lobe beaming JA and Northern Pacific
>>>a SW lob beaming Long Path to VK/ZL
>>>a SE lobe beaming the Middle East

That’s about as good as it gets, short of having a rotary beam!

Of course any object in the vicinity of the antenna might affect its radiation pattern.

Since I have no experience with a triangle loop, I won't bother you with my speculation on how it might work. I prefer to talk on antennas with which I have a lot of experience.

If I were you and had the space, I would try a full wl on 80m. Something like 275 ft. Everett, N8CNP just put one up and I put up the details of his loop on my web site. See: www.dj0ip.de/loop-antennas/8-band-horizontal-loop/

Hi Rick & All,

Yeah, I'm viewing it all as antenna cost and if you figure the cost per band, per year of use, it'll amatorize.

I'm still playing with my too low loop and won't really know much until I get the stand alone balun to play with, but a few questions still lurk.

Height still is a question, what is the minimum workable? I think I do want 80 meter as I can tune to it at my current wire length and I was surprised it was quite active later in the evening, seemed like friendly groups, the one group that tolerated my weak intrusion were very friendly and patient pulling me out of the background noise. 34' is the highest UPS shippable mast I can find, but the tilt up masts from sch 40 pipe aren't off the table either.

Wooden poles - are you talking simply trees with the branches removed, or pressure treated utility poles? What diameter?

Shape - my current loop is a rectangle about 65' on the long edges and 30' on the short edges. Square better?

Feedpoint - I've read the feedpoint can affect the directivity? I'm near Lincoln, Nebraska so I'd think I'd prefer to orientate towards Europe?

Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?.

First ... cut it for 3.4 ... and then fine tune it (as you sure know it is easier cutting a wire then adding a length to it)

My guessing is that you will have it tuned then to 3.55-3.6 (should give resonance on 7.15-7.2)

Measure it with a homebrewed 1:4 ... (if you can not switch your tuner to bypass with balun still used) ..

Check all bands (yes you WIIL use it also on higher bands!!)

I would not cut it tooo short (not tooo high in resonance) ... more towards 3.5-3.55

Reason ... higher would shift the harmonics out of the band (7.2x2=14.4 ... 7.2x3=21.6 ... etc.)

Good luck in finding your "sweet spot" ... grin

Dg9bfc

Sigi

Ps I use a topbandloop (168m) on ALL BANDS

Send 4 of those poles over here Rick!!

I currently run a 300 ft or so horizontal loop up 30 ft….using channel master so called 40 ft telescoping metal poles.

I can work 160 thru 10 meters with loss of efficiency, of course, on 160 meters.

I feed it with 500 ohm home-brew feeders via a LL tuner by PA0LL that uses ganged roller inductors….I have tried other commercial transmatches with much less desirable results, including
Palstar AT2K, AT2KD, and TT 238 series of transmatches.

The LL tuner simply handles matching better…with the exception of a home-brew link coupled transmatch.

Best bet for auto tuner operation…get a SGC 230 for barefoot operation and connect one side of the twin lead to SGC tuner ground and the other to the SGC rf output….do not install any kind of balun on the output, but install rf chokes on the coax input and dc line to the SGC.

I have an older SGC 230 and it will handle 160 thru 10 meters with my short loop nicely,.

The only reason I am not using it now is because I have incorporated a little 600 watt solid state amp into the station.

I have plans to expand the loop to close to 500 ft by this fall, just to increase the efficiency on 160.

>
> >1. The number one most important job of the balun is to keep common mode current out of the matchbox. With a perfect 1:1 SWR, the common mode impedance (CMI) of a 1:1 Guanella and a 4:1 Guanella Balun are close to being the same. As the SWR rises, the CMI of the 4:1 quickly goes to hell in a hand basket, whereas the 1:1 marches on like a super trooper, maintaining high CMI.

>
> Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?.

4701. Military Surplus Fiberglass Poles - WHERE are they?

Yahoo group: SkyWires
Date: 2015-06-11 20:14:50 UTC
From: slr_65@...
Topic: 4701 Message: 4701

Discussing this with some fellow local amateurs, and doing some net research, I just keep seeing references to the inexpensive military surplus fiberglass poles and eBay is usually referenced.

They're supposed to be 4' long and swedged on one end and stack on top of each other. If the joints have a couple screws sunk in them and they're guyed well they are supposed to be workable for temp installs.

I doubt I would want to go with four of these for a loop, but if inexpensive enough I thought I might actually put a tall center up for a Vee support for a transmit antenna and then use my low loop for a receive antenna as my Kenwood has a receive antenna option.

I'll be darned if I can find these anywhere though. It's very frustrating to me as it's hard enough to read and search after search after search just doesn't spit it out.

Am I not using the right search terms? If so, WHAT DO I SEARCH FOR? Or, were these commonly available a few years ago and now the supply has dried up?

4702. Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

OK, Let's assume I can override the urge to use what's in the tuner ;-) and mount the model 1171 near my coax pass thru in the shack and jumper to the pass thru with 3' of RG-213 or RG8x. Eliminating the hole in the wall I was about to drill/cut also!

The K5RCD site tells me to calc length to lowest possible frequency to be used (3.55Mhz) and then subtract 4% for lower velocity factor of the insulated wire. I end up with just a touch under 272' of wire. So that's what I'll try to hang. I originally looked at getting 510' of wire up (top of 160m) but just can't do it with house and power drop located in my space. I probably could get 385' of wire up but unless you say different I'm going with about 272'. I have a NA4RR hex beam up above the garage/shack here so I doubt I will use this loop for anything higher than 40m but one never knows.

Any thoughts on feeding at the middle of the East side (w/ ~55' of window line, no metal poles) vs the NE corner (~30' of same up to a pulley on the metal pole the Hex is on)?

Unfortunately my shack location is in the NE corner of my lot and except for the occasional Caribbean or Mexican contact all of where I need it to work is WNW clockwise to due East (I'm thinking best feed corner would be diagonally opposite from the shack) 100ft away and not very practical). Does feeding it in the middle of the East leg (going N to S) make it stronger across the rectangle to the West vs stronger to the SW feeding it in NE corner? Not much of anything to the SW of me. Are the differences too small to worry about?

Auch mein Freund,
Thanx again for the great info and support.

Skip

4704. AW: AW: [SkyWires] Steve's install strategy, thinking out loud

Yahoo group: SkyWires
Date: 2015-06-11 20:47:12 UTC
From: siegfried jackstien
Topic: 4657 Message: 4704

Ok .. if it is really spare (and you can make a good deal) ... then sell it (and buy some equipment) ... but do not spent tooo much just for a wire antenna ... save that for a rotator and a beam (or other things)

A wire antenna does not cost much more as the wire (and some insulators)

If you have room ... then build a topbandloop (old timers say if you can not make it high ... then make it long)

... but I do not know your local situation ... so maybe you just NEED some poles (what about some used utility poles?!?)

Or build a frames from wood (cheap and should last for years)

Dg9bfc

I like those tilt ups, I really do, just looks like the best bang for the buck. Removal wouldn't be that difficult if one gave thought to the base base when creating it so it could be easily lifted off and the rest left and buried. *That is what I did*.

The only real issue is the length of the pole it's self, I wonder if coupling smaller lengths would be strong enough? *Strong enough for what?? I had a 3 element 15M mono band antenna and a CD-45 ll rotor on it.*

Ah heck Denton, you□re 4 days too late!

I could have sent them back in Air Force One.
Obama was over here this past weekend for the G7 meeting!

Nice to see you□re on here too. I just joined 2 days ago.

You're a very lucky man to own one of Kees' LL tuners!
Just about the best thing going now days, unless you build your own
link-coupled tuner!

Send 4 of those poles over here Rick!!

I currently run a 300 ft or so horizontal loop up 30 ft .using channel
master so called 40 ft telescoping metal poles.

I can work 160 thru 10 meters with loss of efficiency, of course, on 160
meters.

I feed it with 500 ohm home-brew feeders via a LL tuner by PA0LL that uses
ganged roller inductors .I have tried other commercial transmatches with
much less desirable results, including
Palstar AT2K, AT2KD, and TT 238 series of transmatches.

The LL tuner simply handles matching better with the exception of a
home-brew link coupled transmatch.

Best bet for auto tuner operation get a SGC 230 for barefoot operation and
connect one side of the twin lead to SGC tuner ground and the other to the
SGC rf output .do not install any kind of balun on the output, but install
rf chokes on the coax input and dc line to the SGC.

I have an older SGC 230 and it will handle 160 thru 10 meters with my short
loop nicely,.

The only reason I am not using it now is because I have incorporated a
little 600 watt solid state amp into the station.

I have plans to expand the loop to close to 500 ft by this fall, just to
increase the efficiency on 160.

Unfortunately you are right; these have become very scarce.
I haven’t seen them on ebay, except for onsies, twosies, for a couple of years now.

They were actually tent poles.
I guess the army doesn’t sleep in tents anymore.

I picked up a bag of about 12 of these while in the states a few years ago.
I use them often for temporary use.

One trick to reduce their wobbling is to epoxy them together in sets of 2’s.
That makes for one steady 8’ long pole segment. Still short enough to store anywhere.
Then when you mate them together, tape a couple of strips of electrical tape to the swaged ends.
This gives them a snugger fit.
These two actions really improves the rigidity of this kind of pole.

However, the trick is to find them now days.

Subject: [SkyWires] Military Surplus Fiberglass Poles - WHERE are they?

Discussing this with some fellow local amateurs, and doing some net research, I just keep seeing references to the inexpensive military surplus fiberglass poles and eBay is usually referenced.

They're supposed to be 4' long and swedged on one end and stack on top of each other. If the joints have a couple screws sunk in them and they're guyed well they are supposed to be workable for temp installs.

I doubt I would want to go with four of these for a loop, but if inexpensive enough I thought I might actually put a tall center up for a Vee support for a transmit antenna and then use my low loop for a receive antenna as my Kenwood has a receive antenna option.

I'll be darned if I can find these anywhere though. It's very frustrating to me as it's hard enough to read and search after search after search just doesn't spit it out.

Am I not using the right search terms? If so, WHAT DO I SEARCH FOR? Or, were these commonly available a few years ago and now the supply has dried up?

CQ, CQ, SE Nebraska,

I have the aluminum versions holding an 8.5' 2m omni at 29' AGL on garage roof for 3 years. Bottom is in a tripod. One set of guy wires at the joint between the top two sections and then a 14" piece of the fiberglass version that the antenna actually clamps to (puts the guys about 4.5' below the top of the pole). The top two joints in the aluminum pole are cross bolted with SS hardware.

In the past I also had a 2m quad on the aluminum sections up at 39' coming from a hinged spike in the ground behind the garage, clamped at the peak of the gable roof and then two sets of guy wires at joints above. All joints above roof peak cross bolted. I used to find bags of these things at the hamfests as recently as a year and a half ago. Big fest this weekend in Dallas so I'll ask the guys to check to see if they're still around.

They are actually a bit short of 48" each and I still have the old 10 section Quad pole in 3 sections behind the garage (painted light grey) with the guy plates still in it. As I recall the smooth ones are actually a bit heavier duty than the ribbed ones. Lemme know if you need exact dimensions.

4710. RE: [SkyWires] Steve's install strategy, thinking out loud

Yahoo group: SkyWires
Date: 2015-06-11 21:23:58 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4657 Message: 4710

Hi Skip,

Between the balun and the matchbox, I strongly recommend using ONLY RG-213 or LMR-400. Even though RG8x can handle your power level, it might break down under the high voltage presented on some bands.

I STRONGLY RECOMMEND DOING WHAT SIGI SAID!

Don’t cut it ‘exactly’ to any formula. Cut it longer than the formula dictates, and forget the 4% as well.
Put the loop up, measure your resonance on the desired bands, and then trim in small increments.

You know the gig: “What's going on? I’ve cut it 3 times and it’s still too short!” (hi)

As for recommending where to feed it, well again we might ask Sigi to model it for you. I’m pathetic at modeling. He's good at it. I’m a hands-on field guy.

It is not going to make any difference on 80m but on 40 or 30m it will make a bit of difference where you feed it.

I have never fed a horizontal loop in the middle, only in one of the corners. I might speculate on how I think it would work, but most of the time when I do that, I end up looking foolish. Instead I will stick to talking about things I have done and know work. If I don't know, I won't guess.
That's what models are for.

I wanted to take a look at your QTH on googlemaps, but you only show a PO box on QRZ.com.

Subject: Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

OK, Let's assume I can override the urge to use what's in the tuner ;-) and mount the model 1171 near my coax pass thru in the shack and jumper to the pass thru with 3' of RG-213 or RG8x. Eliminating the hole in the wall I was about to drill/cut also!

The K5RCD site tells me to calc length to lowest possible frequency to be used (3.55Mhz) and then subtract 4% for lower velocity factor of the insulated wire. I end up with just a touch under 272' of wire. So that's what I'll try to hang. I originally looked at getting 510' of wire up (top of 160m) but just can't do it with house and power drop located in my space. I probably could get 385' of wire up but unless you say different I'm going with

about 272'. I have a NA4RR hex beam up above the garage/shack here so I doubt I will use this loop for anything higher than 40m but one never knows.

Any thoughts on feeding at the middle of the East side (w/ ~55' of window line, no metal poles) vs the NE corner (~30' of same up to a pulley on the metal pole the Hex is on)?

Unfortunately my shack location is in the NE corner of my lot and except for the occasional Caribbean or Mexican contact all of where I need it to work is WNW clockwise to due East (I'm thinking best feed corner would be diagonally opposite from the shack) 100ft away and not very practical). Does feeding it in the middle of the East leg (going N to S) make it stronger across the rectangle to the West vs stronger to the SW feeding it in NE corner? Not much of anything to the SW of me. Are the differences too small to worry about?

Auch mein Freund,
Thanx again for the great info and support.

4711. Re: [SkyWires] horizontal loop resonence

Yahoo group: SkyWires
Date: 2015-06-11 21:25:23 UTC
From: Evan Rolek
Topic: 4657 Message: 4711

All,

Based upon near field (field strength meter in the shack, signal reports within a mile of my QTH) and far field (stations 50-600 miles away, switching back and forth over several months), I could determine no significant difference in received nor transmitted signal reports between a resonant and "non-resonant" horizontal loop for 40 or 80 meters. What am I missing here by not having a resonant horizontal loop?

73,

Evan, K9SQG

Hello Skip,

The 80m loop sounds good. No, it sounds GREAT.

When running openwire, it makes absolutely no difference whether you tune it for 3.6 or 3.9 MHz.
The QSO partner at the other end will notice about as much as you and I notice when a sack of rice falls over in China.

Performance on 40m is going to be outstanding. As I said earlier, a 2 wl loop is one of my favorite antennas overall.

With Coax it would be a different story. Here I would always choose a resonate frequency 3.6 MHz or even lower (i.e. 3.55 MHz) so that the harmonics fall within the upper ham bands. With 3.9 MHz, all of its harmonics are outside of the higher bands. The SWR may be a bit high on 75m, so use a tuner.

The AT2K is an outstanding tuner, but I recommend not using its built-in balun.
In later models, Palstar removed the balun and went to external baluns.
They offer both a 1:1 and 4:1 external balun but the 1:1 is the better choice.

The very best kind of balun to ALWAYS use when feeding openwire fed antennas is a 1:1 Guanella balun.
I know most people believe a 4:1 is better but it’s not. That is a myth, nothing more.
For the following two reasons:

>1. The number one most important job of the balun is to keep common mode current out of the matchbox. With a perfect 1:1 SWR, the common mode impedance (CMI) of a 1:1 Guanella and a 4:1 Guanella Balun are close to being the same. As the SWR rises, the CMI of the 4:1 quickly goes to hell in a hand basket, whereas the 1:1 marches on like a super trooper, maintaining high CMI.

>2. Except for 160m, your AT2K has less than 10% loss with impedances from 12.5 Ohms up to over 1600 Ohms. There is zero benefit in using a 4:1 transformer in front of it to drop the impedance.

As for "which external balun", well I wind my own but if I were to buy one, the only one I would buy is the Balun Designs Model 1171. It's not cheap, but neither was the Palstar or any other quality product.
See: http://www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/?page_context=category&faceted_search=0

It is important for people to realize that:

>1. there are many different kinds of baluns because we have so many different applications for them.

>2. There is an awful lot of crap being offered for sale and many times the people selling them have no clue what they are talking about. So do your own due dilligance.

>3. One of the best ways to shoot yourself in the foot is to skimp on the balun. Not only can it end up being lossy and eating half your power, it can also be the cause of many unwanted side effects, such as TVI, hot mics, etc., simply because it is not doing the job it was supposed to do - even though it cost a lot of money. Sometimes that's because the

product itself is crap, but often it is a good product but not the right one for the job at hand.

With a good external balun Skip, you're going to be very pleased with your loop.

To: SkyWires@yahoogroups.com
Subject: Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

Thank you VERY much for the tuner sheet and the good info.

I'm about to string up a 75m/80m loop (insulated 14awg stranded copper) and side or corner feed it with 450 ohm window line directly (thru the wall) into the back of my Palstar AT2K (old one with a 4:1 current balun in it).

It's PRIMARY function will be to replace the 75m coil loaded section of my Alpha-Delta DX-CC dipole for use on 3.9MHz SSB. However I occasionally run, via tuner, down on the digi portion of the band ~3.58MHz.

It would also be a REAL bonus if the loop was also good on 7.19Mhz (my primary band segment) to supplement the dipole.

The loop will have a high corner (possible feed point) of around 10.5m with it slopping away to ~7.2m at the other 3 corners and will be slightly rectangular with it longer E-W than N-S. I could also feed it at 7.4m high on the east leg that's running N to S due to it's close proximity to an unused pulley I have in a tree there.

Finally to the questions. Should I cut this for 3.58MHz or 3.9Mhz considering it's intended mission? Anything to consider to increase odds of it out performing my dipole on 7.19Mhz? Any other suggestions?

Tschuess, Skip

On 06/11/2015 07:18 AM, 'Rick - DJ0IP / NJ0IP' Rick@... [SkyWires] wrote:

Steve

The trees I’m speaking of are just trees with bark and limbs removed.
They may be painted or oiled but they are not pressure treated utility poles.

I live in Bavaria (even though it is near Frankfurt) and here we have a tradition of raising a May Tree (Maibaum) on the first of May, each year. Every city, town or village does that. We can buy trees untreated or already painted in white and blue stripes.

Here is what such an event looks like (hope the link works):
http://www.sueddeutsche.de/muenchen/pflicht-fuer-bewohner-der-stadt-was-echte-muenchner-im-fruehling-machen-1.1309161-6

I understand you are vision impaired but I don't know to what extent.
If you are unable to see the picture, perhaps someone can describe it to you.

Obviously your trees would be a wee bit shorter (hi).
As you can tell by the picture, the boys have their act together.
They put these up by hand; pure manpower, using only sticks to push it up.

Lots of people put these in their yard, but of course mostly only about 30 ft. high.

Now to the ELECTRICAL PART:

If you wish to feed your loop with coax, it is probably better to have it very close to resonance on either 80m or 40m.
This means about 275 ft. or 137 ft. This keeps the impedance on harmonic bands close to 100 to 150 Ohms. You can then use a 2.5:1 or 4:1 balun to match them.

If you are feeding with Openwire feedline and have a good antenna tuner, then having it resonant on the ham band is not so important.

RADIATION PATTERN:

I have only built and used square loops. I have never made mine in a triangle or some other shape.

>>>On the fundamental, you get a fairly round 360 degrees radiation pattern, and covering medium to high angle radiation angles.

>>>On the second harmonic (i.e. 40m for an 80m resonant full wave loop), you get 4 major lobes, one off of each corner. Its high angle radiation is reduced a lot but still fairly good in practice. There is also good radiation off the sides, though not so strong as off of the 4 corners. These are fairly wide lobes. I find a 2 wl long loop to be one of the best omni-directional antennas going.

>>>On the 4th harmonic and higher, as well as the 3rd harmonic for a 40m loop, the major lobes are horizontally a bit narrower and vertically, radiate much lower, which is outstanding for DX. HERE IN EUROPE THIS IS BENEFICIAL!

If I build my 80m loop with its wires running exactly North-South and East-West, then on the higher bands, I get:
>>>a NW lobe beaming Stateside
>>>a NE lobe beaming JA and Northern Pacific
>>>a SW lob beaming Long Path to VK/ZL
>>>a SE lobe beaming the Middle East

That’s about as good as it gets, short of having a rotary beam!

Of course any object in the vicinity of the antenna might affect its radiation pattern.

Since I have no experience with a triangle loop, I won't bother you with my speculation on how it might work. I prefer to talk on antennas with which I have a lot of experience.

If I were you and had the space, I would try a full wl on 80m. Something like 275 ft.
Everett, N8CNP just put one up and I put up the details of his loop on my web site.

Subject: RE: [SkyWires] Steve's install strategy, thinking out loud

Hi Rick & All,

Yeah, I'm viewing it all as antenna cost and if you figure the cost per band, per year of use, it'll amatorize.

I'm still playing with my too low loop and won't really know much until I get the stand alone balun to play with, but a few questions still lurk.

Height still is a question, what is the minimum workable? I think I do want 80 meter as I can tune to it at my current wire length and I was surprised it was quite active later in the evening, seemed like friendly groups, the one group that tolerated my weak intrusion were very friendly and patient pulling me out of the background noise. 34' is the highest UPS shippable mast I can find, but the tilt up masts from sch 40 pipe aren't off the table either.

Wooden poles - are you talking simply trees with the branches removed, or pressure treated utility poles? What diameter?

Shape - my current loop is a rectangle about 65' on the long edges and 30' on the short edges. Square better?

Feedpoint - I've read the feedpoint can affect the directivity? I'm near Lincoln, Nebraska so I'd think I'd prefer to orientate towards Europe?

Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?.

Resonance. (that’s all)

It is a myth that resonant antennas radiate better than non-resonant antennas.
In fact we often intentionally make antennas non-resonant so as to get more gain or a better match.

Especially with openwire-fed, center-fed dipoles, we often intentionally make them a bit longer or shorter than resonance so as to avoid the high impedance on even harmonic bands. That doesn't make them work less efficiently, but it does make them much easier to match.

Wish I had a dollar for every ridiculous myth floating around!

Honestly these ARE questions:
What about ability to bypass tuner on the tuned band / Freq? Isn't that good for a bit of signal? Especially when coax fed?

That is why I tuned my loop (cut to resonance) with the tuner bridged ...

Not that the signal is different when I use the tuner ... but it is just not needed (that half of a db loss would nobody notice)

... the main advantage is ... if you wanna use an amp (but do not have a high power tuner)

If antenna is matched then no need for a tuner (and a slight mismatch can be tuned away with the pi section of a tube amp)

I have 48 of them in my garage. You'll see them put to good use on my QRZ page.
Don't put screws in them. You'll just weaken them. SS radiator clamps will hold them.

Topic: 4657 Message: 4718

Fellow enthusiasts,

Interesting comments about resonance, or lack of it, with a horizontal loop.

I don't mind a little loss through an antenna tuner. With window line, I'm still better off than with coax. Plus the tuner significantly reduces harmonics when transmitting, and affords some attenuation of other, undesirable signals within the band of interest on receive. The noise reduction with the loop is a big benefit for me. For my operating needs, I'm content with my installation but still strive for improvements from time to time.

So what is good for my installation and needs might not work for others. But it is still nice to exchange ideas, that's one way we can learn,

From: slr_65@...
Topic: 4719 Message: 4719

I've obviously been looking at mast options and I ran across this site last night.
http://www.eham.net/articles/33609
I'll save you from having to read through it all.
*) Basically it's not really a push up" mast, it's a "stackable" mast along the lines of the now hard to find military fiberglass masts.
*) He's using 1-1/2" EMT electrical conduit.
*) He's coupling it with some close fitting Drawn Over Mandrel tubing, the couplers extend onto each section about 5".
*) If you use 10' sections he installs a 6" stiffener in the middle of the length, else they tend to bend there.
*) He suggests just cutting the sections into 5' pieces and coupling them.

Interesting, but the DOM tubing is expensive enough to make other options more attractive.

I found another web page referencing this one, I thought I bookmarked it, but darned if I can find it again even after a long search of my history...vision impairment and LOTS of searches don't make it too easy to locate a specific page again!

Oh well, the gist of the second page was:
*) They also used 1-1/2" EMT.
*) They also cut it into 5' sections, mostly for ease of assembly, but also mentioned it was a bit stronger when coupled smaller sections were used.
*) They used the normal EMT connectors though. They are shorter, but they said they worked fine.
*) They JB Welded one connector on each section.
*) They used the normal set screw and then also drilled another hole through the connecter and section and would tap it and install a machine screw.
*) They were using the same guy wire plates as the first article.
*) They guyed it every 10'

The EMT in town is $12 a 10' section, so $42 per 35'.
The couplers are about $2 each, so $12 for couplers.
So $54 plus I haven't priced JB Weld or the guy wire rings. Guy wire costs too, plus you're tripping over them.

I don't think I'm leaning this way, I'm thinking the tilt up looks better, but I thought I'd write this up a bit in case anyone else is looking for something inexpensive and portable and has found the old military fiberglass poles are no longer out there.

Topic: 4657 Message: 4720

GM Evan,

Provided you make intelligent matchbox choices, then you are right.
And as your closing statement points out, the mileage definitely does vary from one installation to the next.

There are many different matchbox technologies and all “claim” to be the best thing since sliced bread. Many can even show at least one example where that may even be true.

The truth is, we have a diverse portfolio of antenna applications and the matching requirements are all over the map. The single biggest problem we have today is "the mindset of the operator."

Seems Joe Ham thinks he ought to be able to do everything with just one matchbox, if he buys a good one. NOT! No matchbox on the planet can do that.

If we would remove the 160m band and the 10m and 12m band from the scenario, then we could come close for many applications (not all). But it is impossible to build a matchbox that will match all impedances (from 5 Ohms to 4000 Ohms) on all bands.

Different strokes for different folks.
Different matchbox technologies for different applications.

So it is wrong to generalize and say that a matchbox has low loss or high loss.
The right matchbox will have low loss and the wrong matchbox will have high loss.

Almost all matchboxes have a “sweet spot” where they perform efficiently.
They match anything within that range with so little loss that the QSO partner at the other end will never notice any difference.”

But they also ALL have weak spots where the efficiency sinks like a rock, and in some cases, can eat up over 50% of the power.

The ARRL has been testing antenna tuners for the past 15 years to determine their matching range and efficiency. Their test results were published in QST during this time period.

Each test typically compares 3 to 5 similar matchboxes and the results are published in tables.
These table clearly show the sweet spot for each matchbox.

I spent countless hours going through all of these test reviews and summarizing the results into one MONSTER Excel spread sheet. This gives the viewer an overview of most of the ATUs on the market.

You will find this file (Matchbox Shoot-Out) on my web site, here:
http://www.dj0ip.de/antenna-matchboxes/matchbox-shoot-out/

NOTE: This spreadsheet is no substitute for reading the original QST review. It is just a starting point to create your own short list of ATUs that might be what you are looking for. Once you have your list of 3 or 4 tuners, THEN read the original review and make an intelligent choice.

About the dumbest thing anyone can do is choose a matchbox because it matches the transceiver line or because Dave down the street has one and likes it. That's about like choosing your XYL based on the color of clothes she was wearing the day you met her. ;-)

Do your own due diligence and judge products on their ability to solve your own requirements, not by how popular they on eham.

Skip,

I have copied Sigi on this reply. Let’s keep him in the loop! (pun intended – hi)

He’s my sanity check because sometimes I make mistakes too.

First of all, it will make no difference if you have 3’ or 6’ of coax between the Balun and the tuner.

Just be sure it is of the best quality you can get.

I have attached a 2-page PDF.

Let’s begin on page 2.

It shows your QTH (I hope) and two scales in meters.

My Googlemaps shows meters.

Start by defining your property lines.

For instance, on the front side does your property end at about 40m or 50m?

On the east side, does it end at 40m?

Once we know that, we can add property lines to page 1 and then draw your antenna in.

Then we proceed by you telling us what direction your main interest is.

I think you said WNW to due East, which would include North. Not sure what you might work to the north, other locals on 80 and for that it makes no difference where we place the feedpoint.

We’ll continue one step at a time.

Subject: Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

OK, Let's assume I can override the urge to use what's in the tuner ;-) and mount the model 1171 near my coax pass thru in the shack and jumper to the pass thru with 3' of RG-213 or RG8x. Eliminating the hole in the wall I was about to drill/cut also!

The K5RCD site tells me to calc length to lowest possible frequency to be used (3.55Mhz) and then subtract 4% for lower velocity factor of the insulated wire. I end up with just a touch under 272' of wire. So that's what I'll try to hang. I originally looked at getting 510' of wire up (top of 160m) but just can't do it with house and power drop located in my space. I probably could get 385' of wire up but unless you say different I'm going with about 272'. I have a NA4RR hex beam up above the garage/shack here so I doubt I will use this loop for anything higher than 40m but one never knows.

Any thoughts on feeding at the middle of the East side (w/ ~55' of window line, no metal poles) vs the NE corner (~30' of same up to a pulley on the metal pole the Hex is on)?

Unfortunately my shack location is in the NE corner of my lot and except for the occasional Caribbean or Mexican contact all of where I need it to work is WNW clockwise to due East (I'm thinking best feed corner would be diagonally opposite from the shack) 100ft away and not very practical). Does feeding it in the middle of the East leg (going N to S) make it stronger across the rectangle to the West vs stronger to the SW feeding it in NE corner? Not much of anything to the SW of me. Are the differences too small to worry about?

Auch mein Freund,
Thanx again for the great info and support.

Skip

On 06/11/2015 02:07 PM, 'Rick - DJ0IP / NJ0IP' Rick@... [SkyWires] wrote:

Hello Skip,

The 80m loop sounds good. No, it sounds GREAT.

When running openwire, it makes absolutely no difference whether you tune it for 3.6 or 3.9 MHz.
The QSO partner at the other end will notice about as much as you and I notice when a sack of rice falls over in China.

Performance on 40m is going to be outstanding. As I said earlier, a 2 wl loop is one of my favorite antennas overall.

With Coax it would be a different story. Here I would always choose a resonate frequency 3.6 MHz or even lower (i.e. 3.55 MHz) so that the harmonics fall within the upper ham bands. With 3.9 MHz, all of its harmonics are outside of the higher bands. The SWR may be a bit high on 75m, so use a tuner.

The AT2K is an outstanding tuner, but I recommend not using its built-in balun.
In later models, Palstar removed the balun and went to external baluns.
They offer both a 1:1 and 4:1 external balun but the 1:1 is the better choice.

The very best kind of balun to ALWAYS use when feeding openwire fed antennas is a 1:1 Guanella balun.
I know most people believe a 4:1 is better but it’s not. That is a myth, nothing more.
For the following two reasons:

>1. The number one most important job of the balun is to keep common mode current out of the matchbox. With a perfect 1:1 SWR, the common mode impedance (CMI) of a 1:1 Guanella and a 4:1 Guanella Balun are close to being the same. As the SWR rises, the CMI of the 4:1

quickly goes to hell in a hand basket, whereas the 1:1 marches on like a super trooper, maintaining high CMI.

>2. Except for 160m, your AT2K has less than 10% loss with impedances from 12.5 Ohms up to over 1600 Ohms. There is zero benefit in using a 4:1 transformer in front of it to drop the impedance.

As for "which external balun", well I wind my own but if I were to buy one, the only one I would buy is the Balun Designs Model 1171. It's not cheap, but neither was the Palstar or any other quality product.
See: http://www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/?page_context=category <http://www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/?page_context=category&faceted_search=0> &faceted_search=0

It is important for people to realize that:

>1. there are many different kinds of baluns because we have so many different applications for them.

>2. There is an awful lot of crap being offered for sale and many times the people selling them have no clue what they are talking about. So do your own due dilligance.

>3. One of the best ways to shoot yourself in the foot is to skimp on the balun. Not only can it end up being lossy and eating half your power, it can also be the cause of many unwanted side effects, such as TVI, hot mics, etc., simply because it is not doing the job it was supposed to do - even though it cost a lot of money. Sometimes that's because the product itself is crap, but often it is a good product but not the right one for the job at hand.

With a good external balun Skip, you're going to be very pleased with your loop.

Tschuess mein Friend!

To: SkyWires@yahoogroups.com
Subject: Re: [SkyWires] Steve's install strategy, thinking out loud

Rick,

Thank you VERY much for the tuner sheet and the good info.

I'm about to string up a 75m/80m loop (insulated 14awg stranded copper) and side or corner feed it with 450 ohm window line directly (thru the wall) into the back of my Palstar AT2K (old one with a 4:1 current balun in it).

It's PRIMARY function will be to replace the 75m coil loaded section of my Alpha-Delta DX-CC dipole for use on 3.9MHz SSB. However I occasionally run, via tuner, down on the digi portion of the band ~3.58MHz.

It would also be a REAL bonus if the loop was also good on 7.19Mhz (my primary band segment) to supplement the dipole.

The loop will have a high corner (possible feed point) of around 10.5m with it slopping away to ~7.2m at the other 3 corners and will be slightly rectangular with it longer E-W than N-S. I could also feed it at 7.4m high on the east leg that's running N to S due to it's close proximity to an unused pulley I have in a tree there.

Finally to the questions. Should I cut this for 3.58MHz or 3.9Mhz considering it's intended mission? Anything to consider to increase odds of it out performing my dipole on 7.19Mhz? Any other suggestions?

Tschuess, Skip

On 06/11/2015 07:18 AM, 'Rick - DJ0IP / NJ0IP' Rick@... [SkyWires] wrote:

Steve

The trees I’m speaking of are just trees with bark and limbs removed.
They may be painted or oiled but they are not pressure treated utility poles.

I live in Bavaria (even though it is near Frankfurt) and here we have a tradition of raising a May Tree (Maibaum) on the first of May, each year. Every city, town or village does that. We can buy trees untreated or already painted in white and blue stripes.

Here is what such an event looks like (hope the link works):
http://www.sueddeutsche.de/muenchen/pflicht-fuer-bewohner-der-stadt-was-echte-muenchner-im-fruehling-machen-1.1309161-6

I understand you are vision impaired but I don't know to what extent.
If you are unable to see the picture, perhaps someone can describe it to you.

Obviously your trees would be a wee bit shorter (hi).
As you can tell by the picture, the boys have their act together.
They put these up by hand; pure manpower, using only sticks to push it up.

Lots of people put these in their yard, but of course mostly only about 30 ft. high.

Now to the ELECTRICAL PART:

If you wish to feed your loop with coax, it is probably better to have it very close to resonance on either 80m or 40m.
This means about 275 ft. or 137 ft. This keeps the impedance on harmonic bands close to 100 to 150 Ohms. You can then use a 2.5:1 or 4:1 balun to match them.

If you are feeding with Openwire feedline and have a good antenna tuner, then having it resonant on the ham band is not so important.

RADIATION PATTERN:

I have only built and used square loops. I have never made mine in a triangle or some other shape.

>>>On the fundamental, you get a fairly round 360 degrees radiation pattern, and covering medium to high angle radiation angles.

>>>On the second harmonic (i.e. 40m for an 80m resonant full wave loop), you get 4 major lobes, one off of each corner. Its high angle radiation is reduced a lot but still fairly

good in practice. There is also good radiation off the sides, though not so strong as off of the 4 corners. These are fairly wide lobes. I find a 2 wl long loop to be one of the best omni-directional antennas going.

>>>On the 4th harmonic and higher, as well as the 3rd harmonic for a 40m loop, the major lobes are horizontally a bit narrower and vertically, radiate much lower, which is outstanding for DX. HERE IN EUROPE THIS IS BENEFICIAL!

If I build my 80m loop with its wires running exactly North-South and East-West, then on the higher bands, I get:
>>>a NW lobe beaming Stateside
>>>a NE lobe beaming JA and Northern Pacific
>>>a SW lob beaming Long Path to VK/ZL
>>>a SE lobe beaming the Middle East

That’s about as good as it gets, short of having a rotary beam!

Of course any object in the vicinity of the antenna might affect its radiation pattern.

Since I have no experience with a triangle loop, I won't bother you with my speculation on how it might work. I prefer to talk on antennas with which I have a lot of experience.

If I were you and had the space, I would try a full wl on 80m. Something like 275 ft. Everett, N8CNP just put one up and I put up the details of his loop on my web site.

Subject: RE: [SkyWires] Steve's install strategy, thinking out loud

Hi Rick & All,

Yeah, I'm viewing it all as antenna cost and if you figure the cost per band, per year of use, it'll amatorize.

I'm still playing with my too low loop and won't really know much until I get the stand alone balun to play with, but a few questions still lurk.

Height still is a question, what is the minimum workable? I think I do want 80 meter as I can tune to it at my current wire length and I was surprised it was quite active later in the evening, seemed like friendly groups, the one group that tolerated my weak intrusion were very friendly and patient pulling me out of the background noise. 34' is the highest UPS shippable mast I can find, but the tilt up masts from sch 40 pipe aren't off the table either.

Wooden poles - are you talking simply trees with the branches removed, or pressure treated utility poles? What diameter?

Shape - my current loop is a rectangle about 65' on the long edges and 30' on the short edges. Square better?

Feedpoint - I've read the feedpoint can affect the directivity? I'm near Lincoln, Nebraska so I'd think I'd prefer to orientate towards Europe?

Size - I don't have to stay over the house, I could get into the back yard. I could get a full 80 meter loop there. Though I couldn't fit a 160 meter loop, would there be an advantage to setting the corner posts somewhat further apart to allow the loop to be made a tad bigger than 80 meters requires? Of course smaller loops could also be made within the corners, so being able to over/under size a bit may help with tuning?.

4722. RE: [SkyWires] horizontal loop resonence

Yahoo group: SkyWires
Date: 2015-06-12 09:36:26 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4657 Message: 4722

Those are apples with oranges, Skip.

I do not try to feed non-resonant loops with coax.
If I use a non-resonant loop, then it is fed with openwire.

I only use coax with a resonant antenna.

With resonant antennas, a *good* Balun, and less than 100 ft. of *good*
coax, the loss can be just as low as with openwire.

A *good* tuner will not have enough loss to affect your performance when
measured on the S-meter at the other end of the QSO.

The biggest problem here is, often people don't use the right tuner for this
job. When their signal is down, they blame it on "tuners in general" when
the problem is, they failed to do their due diligence in their selection of
tuners. I equate this one to the soccer mom who buys a Porsche, then
complains because it doesn't have room for the soccer team. Should have
bought a mini-van!

Rick and Fellow Enthusiasts,

So, so correct with what you said below. The QST test results provide a lot of useful insight! Armed with that information, as well as knowing the resistive and reactive components of one's own antenna for the bands of interest, permits one to make an informed decision about which tuners might be acceptable. The specs from the manufacturers border on useless because they rarely mention the inductive and capacitive reactances that the tuner can match, they typically only mention the resistive component.

Too, there is a lot of myth and magic out there along with out and out disinformation. When a statement like "can match a 10:1 SWR" is made, does that mean that it can match a 5 ohm and a 500 ohm load? Typically, matching the low impedances is where a lot of tuners fall down. In addition, there is a lot of hearsay and rumor like "the Johnson Matchbox has very limited matching range". Well, just judging by what the manufacturers say about their respective tuners, yes. BUT note that the Johnson Matchbox was DESIGNED for higher impedance antennas usually fed with open wire line. For my horizontal loops the impedances fall within 110 to 250 ohms resistive components for the bands that I operate and, even given the reactive components, the Johnson KW Matchbox is more than up to the task for matching the antennas! So the issue is, will any given tuner be suitable for my particular antennas on the bands that one operates? And as Rick substantiates, one size does not fit all. Those QST (and ARRL book dealing with just antenna tuners) test figures are great information that, well, you won't find in the ads. For those that prefer the advertising hype, there is plenty out there, hi hi. Thus the decision can be made easily and quickly by using an emotional perspective and just believe what the ads say. And who knows, one might be lucky enough to find out that it works for their particular installation. I'm somewhat boring and would rather make decisions about antenna tuners in a more informed manner by looking at the ARRL's data.

73,

Evan, K9SQG

Subject: RE: [SkyWires] horizontal loop resonance

GM Evan,

Provided you make intelligent matchbox choices, then you are right.
And as your closing statement points out, the mileage definitely does vary from one installation to the next.

There are many different matchbox technologies and all “claim” to be the best thing since sliced bread. Many can even show at least one example where that may even be true.

The truth is, we have a diverse portfolio of antenna applications and the matching requirements are all over the map. The single biggest problem we have today is "the mindset of the operator."

Seems Joe Ham thinks he ought to be able to do everything with just one matchbox, if he buys a good one. NOT! No matchbox on the planet can do that.

If we would remove the 160m band and the 10m and 12m band from the scenario, then we could come close for many applications (not all). But it is impossible to build a matchbox that will match all impedances (from 5 Ohms to 4000 Ohms) on all bands.

Different strokes for different folks.
Different matchbox technologies for different applications.

So it is wrong to generalize and say that a matchbox has low loss or high loss.
The right matchbox will have low loss and the wrong matchbox will have high loss.

Almost all matchboxes have a “sweet spot” where they perform efficiently.
They match anything within that range with so little loss that the QSO partner at the other end will never notice any difference.”

But they also ALL have weak spots where the efficiency sinks like a rock, and in some cases, can eat up over 50% of the power.

The ARRL has been testing antenna tuners for the past 15 years to determine their matching range and efficiency. Their test results were published in QST during this time period.

Each test typically compares 3 to 5 similar matchboxes and the results are published in tables.
These table clearly show the sweet spot for each matchbox.

I spent countless hours going through all of these test reviews and summarizing the results into one MONSTER Excel spread sheet. This gives the viewer an overview of most of the ATUs on the market.

You will find this file (Matchbox Shoot-Out) on my web site, here:
http://www.dj0ip.de/antenna-matchboxes/matchbox-shoot-out/

NOTE: This spreadsheet is no substitute for reading the original QST review. It is just a starting point to create your own short list of ATUs that might be what you are looking for. Once you have your list of 3 or 4 tuners, THEN read the original review and make an intelligent choice.

About the dumbest thing anyone can do is choose a matchbox because it matches the transceiver line or because Dave down the street has one and likes it. That's about like choosing your XYL based on the color of clothes she was wearing the day you met her. ;-)

Do your own due diligence and judge products on their ability to solve your own requirements, not by how popular they on eham.

Subject: Re: [SkyWires] horizontal loop resonance

Fellow enthusiasts,

Interesting comments about resonance, or lack of it, with a horizontal loop.

I don't mind a little loss through an antenna tuner. With window line, I'm still better off than with coax. Plus the tuner significantly reduces harmonics when transmitting, and affords some attenuation of other, undesirable signals within the band of interest on receive. The noise reduction with the loop is a big benefit for me. For my operating needs, I'm content with my installation but still strive for improvements from time to time.

So what is good for my installation and needs might not work for others. But it is still nice to exchange ideas, that's one way we can learn,

73,

Evan, K9SQG

I've been looking at options to get the antenna up higher, it's a perplexing problem to do on a budget...reminds me of a cartoon I saw once, everyone was standing around looking at something and the caption read "I don't know the answer, but I certainly admire the problem!".

4728. Experience with 295' horizontal loop

Yahoo group: SkyWires
Date: 2015-06-13 13:24:09 UTC
From: James Allender
Topic: 4728 Message: 4728

Greetings to all. I have really enjoyed all of the recent posts concerning horizontal loop antennas, tuners, baluns, etc. I thought I would share some simple experiences that I have had with this antenna.

I have a 295' or so loop strung around my back yard, fed with 450 ohm line, connected to a little Elecraft T1 tuner, and then into my K2 rig, running never more than 12 w or so. The loop has four sort of equal sides; it is hung on little ropes and pulleys from "trees of opportunity." Two of the corners are about 15' high, the other two are only about 8' high. (I do live on a hill, though.)

I am surprised at how well this setup works. It tunes easily on all bands from 80 to 10 m. I have used it on 40, 30, 20, 17, and 15 m. On 20 m it is comparable to and sometimes better than my 20 m inverted vee with its center elevation at about 35'.

Contacts through the U.S. are no problem on 20 and 15. Europe and central Asia are workable. Far East and Africa - not so much, but that is partly due to my low power. Evening contacts on 40 and 30 are easy enough.

So, for me, this antenna is inexpensive, easy to construct, works on multiple bands, and surprises me with good performance, it spite of its low elevation. I hope my experience will encourage others to give this setup a try!

Still looking at support options. I really think I'm stuck with the Rohn H-50 or something similar.

Many, many posts on the net where guys are doing what I want to do - ground mounted, supported at a first story eave and then up unguyed another 10 feet for sure, sometimes 15 to 20 but they lower them when not in use or bad weather is approaching. They are of course running wire antennas only. Guying is needed for anything more, and even a good idea for wire antennas and I could get a couple on.

This is with the H-50, a truck ship only 50 foot model and since it's only being raised about half or a little more, the inner tubes are reinforcing the outter tubes, so it's really increasing the strength.

The UPS shippable model can only get to 34 feet fully extended, so run it at half and you're only looking at 17' or so with double strength.

Rohn lists two distributors that are 200 miles away from me, I think I'll see if they sell direct and if so then that's about $60 in gas and a few hours of a grumpy wife who probably didn't want to blow a day on a road trip. Buy four and it's only $15 extra each for delivery....if the base price is good.

Still an expensive option, but there's just no high spots on this property.

The tilt ups would be nice, but not portable and not cheap either. with these if we have to move they can come easily.

DIY masts may be doable, I found one guy who does his with EMT....he just splits a section of it and uses it to create the connectors and it works well, but something that doesn't telescope could be a hassle to erect.

Still kicking around options, but it's looking like a beefy telescoping mast is the best option. Relatively portable, relatively easy to mount, easy enough to extend / retract....just expensive...I gures it's a one time cost though, so just amortorize it and go on.

I see a couple of people ask for a PDF file, I copied the web page and created a PDF from it. I'm sending it to you off the list. If you wanted to look at it to make sure nothing got missed, then if you chose to, if it looks ok to you then you could upload that too, and they would have an option.

OK, didn't get my project done today, another amateur in town wanted to try a loop and he DOES have trees.

The thought was to use a wrist rocket slingshot to shoot a nut with a string attached up and over a branch or two.

(I was there mostly for moral support, I couldn't see the shot at all)

Attaching even the lightest string, laying the string out, etc. just doesn't get much altitude.

After cussing and discussing, we're thinking spud gun!

We can't be theonly amateurs to face this though, so what is the preferred method of popping a string over a tall tree?

Still, it was a fun afternoon, even if we didn't get much done.

Last night a couple echolinked in and we played on HF for bit, I did surprisingly well on 80 meter about 600 miles out. Got to Riverside, CA with a respectable signal on 20 meter also, so the low loop is working...it could just work better...

Made for a fun night, two more states off my WAS quest!

How high are you trying to get in the tree?
I guess the Spudgun is the best thing going.
I only have an EZ-Hang.
I can get about 60 ft. with it. That’s usually enough.

Here’s a Tip:

I tie pigtails onto the tiny yellow weight of my EZ-Hang.

I too have difficulty spotting it when it is hanging in a tree.
Since adding Pigtails, it’s much easier to find.

We have a plastic tape-like material here, striped red and white.
It is used to mark off danger areas at construction sites.

It is about 2 inches in diameter.
I cut a piece about 8 inches long, and then I cut it in half, over its length.
This leaves it about 1” wide.
I then tie it to the fishing weight of the EZ-Hang.
BIG improvement. Of course it does limit the height just a tad, but there is no big difference.

That is what I used, 1/2" SS nut and a Zebco fishing reel mounted in a stick. Pull a string back over, then a heaver line with a plastic pulley from a big box home store. I have a window sash weight at each corner of my loop to keep the loop up when the wind blows the trees.

Thanks guys, I knew we weren't the only ones who've faced this!

The trees are linden trees, about 30' high, but with good spreads and they're probably 40' apart with the canopy limbs bumping into each other.

Doing some research and ragchewing about it on the repeater tonight, we're going to try and build a pneumatic launcher, much like a spud gun.

I'll post back how it works and if it works well a link to the one we used (we're still choosing one right now).

Hi Guys,

Thanks for the feedback!

We were pushing the boundaries with a slingshot in town, I think a bow would get some unwanted attention and the fall out zone is a residential neighborhood, so probably not a good idea.

The pneumatic launchers seem to be what most are using.

The tennis ball ones look nice and we do like the idea of a tennis ball projectile, but they're fairly expensive to construct, especially when this won't be used much as it's just temporary...unless it works...HI HI! If it works then it would just need redone if problems creep up. It's just like he's doing portable operations routinely.

We're (well, he's...I'm just moral support here!), leaning towards this relatively cheap and simple design. No fancy electric valves, has a small cheap projectile that's probably pretty safe too, etc..

Has anyone tried this design? If it doesn't work well then making a tennis ball sized one isn't out of the question, but it's just a matter of getting a wire over two trees, the exact path isn't really a concern, so aiming accuracy and stuff just isn't that big of a consideration for this project.

I also use a 1/2" SS Nut but with a standard slingshot I purchased for a few bucks at Mr. Walton's market. I use a spool of yellow colored construction line that's easy to see in the tree, and fan out a sufficient quantity on the ground in front of me before shooting. The last time I used it, it only took three attempts to get the nut through a Y next to the tree trunk about 60 feet up. Didn't cost much, and it works fine for me.

Spud guns are nice but they are costly, and illegal in many places. Wrist rockets require a skill I lack.

I use a spinning rod with 10 pound test line, and a 3 oz fishing weight that I painted Fluorescent Orange. Buy and paint a half dozen, believe it or not, the dang things get lost. Who GNU?

I easily cast over my 60 foot tree, my yard and into my neighbor's yard. I have a row of 7 trees that are about 40 feet high and the row is about 100 foot long. I can cast a line over the top of all of them, if there is no wind. Wind is your enemy, a devious, and spiteful enemy whose sole purpose is to ruin your day.
You might want to use a finger to control the line so it doesn't go too far depending on how forgiving your neighbors are. Any make sure there are no house or car windows nearby, incase you have an errant cast. <---This applies to all methods.

Yes it will work, the only problem is aiming it and quickly turning the valve at the same time. That is why the other design uses a dump valve. Back when I was employed we used a similar design to shoot chickens. Not shot at chickens but chickens as the projectile in aircraft bird strike test.

Wow Chuck,

Shawn and my son both tried nuts of various sizes, fishing line, 1mm flax twine, all laid out etc. and couldn't get any respectable distance, I think my son could've thrown a baseball better. It seemed it was the line as just shooting a nut worked fairly well, though not near the height needed to cross the trees.

We were just using a Daisey sling shot from Wally World though, so perhaps not all slingshots are created equal.

Hi Steve,

I think if a spud gun is illegal then so's a slingshot, bow and arrow, etc..

Basically, if you read the city ordinances none of it is permissible...even your casting....in our city you can only deploy fishing equipment on your own property or designated areas of city property and even at that you must cast only what is necessary to reach the water and can not endanger the public in general. Tossing a lead weight over the trees into the neighbor's yard, near a street and sidewalk without a body of water anywhere in sight probably violates that ordinance.

Ok, so we're scofflaws and intent on violating the law, now it's down to getting it done quickly without notice and with as little risk as possible. That rules out bows, crossbows, etc.. Even slingshots, people don't like to see slingshots in town and frankly, they would take forever for us anyway, they just don't work. That leaves the spud gun. Quick to deploy, they seem to work and work well in just a couple shots, the pucks aren't overly dangerous, etc.. I actually discussed it with a retired cop this morning, he laughed and said they wouldn't ticket such an activity unless we damaged something or hurt someone, and even then only if the victim pressed.

There's actually even an exemption for cable routing tools as many tech companies evidently use pneumatic shooters to run pull strings in large building tunnels and ceilings, he wasn't sure this would qualify, though that's exactly what it's doing. Basically he said do it safe, do it quick and I think the pneumatic spud gun meets that criteria the closest.

If you have plenty of room, the pole and weights and already know how to use them though, then yeah....more power to ya! It obvioulsy works and who can argue with success?!?!

Steve, it sounds like you were using a flingshot rather than a slingshot.
I easily get 60 ft. with my EZ-Hang slingshot.

Wow Chuck,

Shawn and my son both tried nuts of various sizes, fishing line, 1mm flax twine, all laid out etc. and couldn't get any respectable distance, I think my son could've thrown a baseball better. It seemed it was the line as just shooting a nut worked fairly well, though not near the height needed to cross the trees.

We were just using a Daisey sling shot from Wally World though, so perhaps not all slingshots are created equal.

I suspect there are slingshot and then there are slingshot!

We only had one choice in town, a Daisey model. Still, wrist braced, surgical tubing...I wouldn't want to be in front of it!

Looking online, there are many, many models, but they quickly get pricey too, so that puts a pneumatic launcher back into the picture.

If you read the reviews on eham and other sites you'll notice that though the EZ Launch is well reviewed, many reviewers say it's time has past and the pnuematic launchers are the way to go.

We'll be discussing it in a bit. He's working, I'm off work and have time to research...the choices seem to be the simple one with a manual valve. Cheap, should work for the height and accuracy isn't a big concern, again, not trying for a specific spot, just up and over two close trees. On the other hand, for less than $100 it can be easily aimable and maybe more useful in the future. We'll see what he wants to do.

Fun stuff, who knew amateur radio would get you building a spud gun?! HI HI!

Mine is also from wally world , the name is a wrist rocket and it attaches to a board with a fishing real with no problem, I just use a hose clamp , sling shot on top, reel on lower side.

I found plenty of fiberglass poles by under Google.
Here is the one that I think I've seen at Dayton and purchased from him:

Oh, they're out there, they just aren't a bargain any more. When it gets 3/4 of what I could get a Rohn H-50 for it's hard to justify because I could run the Rohn guyless at 20' or less over the house and guys cost too. BTW, I called the distributor for Rohn, they will sell direct, $130 for the mast. $60 in gas to get it, but if I bought two or more then the cost of shipping gets cheap per unit. May even be others around that would want to add on to an order if I'm picking up.

Still working on options...

I found one place in Texas that had them for $20 for a 12 piece set with the spreaders and all....and only $120 shipping!!!! I hate that kinda crap, just give an honest price to start with!

I asked around, it seems that EVERY old ham has at least one set of these in their garage, and they got them dirt cheap, but NO ONE is letting go of them! LOL! They just love 'em!

Well, MY slingshot works. I use one of those slingshots the sporting goods stores sell, the kind with a wrist brace. Then, I attach a Game Tracker (spool of line, flourescent orange, on a spool and holder), attach it to a teardrop shaped fishing sinker. You "shoot" the sinker over a limb, then use it to pull up a thicker line, and then finally the thickest line you'll be using. MY slingshot has gotten things up 50 ft or so, your mileage might vary. BUT know that safety glasses, a spotter, etc. safety precautions are in order.

73,

Evan, K9SQG

OK, didn't get my project done today, another amateur in town wanted to try a loop and he DOES have trees.

The thought was to use a wrist rocket slingshot to shoot a nut with a string attached up and over a branch or two.

(I was there mostly for moral support, I couldn't see the shot at all)

Attaching even the lightest string, laying the string out, etc. just doesn't get much altitude.

After cussing and discussing, we're thinking spud gun!

We can't be theonly amateurs to face this though, so what is the preferred method of popping a string over a tall tree?

Still, it was a fun afternoon, even if we didn't get much done.

Last night a couple echolinked in and we played on HF for bit, I did surprisingly well on 80 meter about 600 miles out. Got to Riverside, CA with a respectable signal on 20 meter also, so the low loop is working...it could just work better...

Made for a fun night, tw o more states off my WAS quest!

Especially THAT kind of slingshots are forbidden here (hunting slingshot)

I used my tennis ball launcher a few dozen times ... and even if such a spudgun is called a weapon here (projectile, barrel, pressure chamber = weapon ... that□s the law here)... it is still a lot safer with a tennis ball as when using a lead weight (regardless if thrown from a slingshot or from a fishing rod)

Only thing that wold be allowed is a tennis ball but thrown with a normal tennis racket

I made some speed tests with my launcher ... and I have below half of the speed a good tennis player reaches

When thrown at an angle sufficient to fly over a 60 foot tree, it goes mostly straight up and then straight down. I do imagine it would smart a little if it were to hit someone in the top of the head, but by then all of it's energy is mostly spent, and you could point out to the victim that, "This is why you should have worn your hat!" hihi

Garden sprayer ... 8 bucks

(nice thing is you have a trigger valve, a pump , a tank and a pressure gauge for that 8 bucks)

Barrel 5 bucks (with the 75mm coupler included)

Most expensive was the valve (around 20 bucks if you use the 1 inch version)

... tennis balls were for free from our local tennis club

... when you make your launcher from such a high number of adaptors, couplers, elbows etc. ... then it will not be cheaper

How high are your trying to go, Steve?

There is another way I often use that is rarely spoken about, yet it is by far the most accurate.

You can place your rope any place you want, down to within about one inch of where you want it.

I like to experiment with wire antennas and have several long telescoping fiberglass poles.

Several are 12m (40') long, and a few are 60' long.

The 40' one is what I use. I usually remove the very top segment, leaving me 37' (plus my own arm's reach) to work with.

I fasten a tiny pulley near the top of the pole and run a thin rope up and back.

I use a large fishing lead weight for the weight and tie some colored tape to it so that I can see it.

Then I simply stand in place, telescope the pole segments up, one at a time, which takes about 60 seconds, then walk the pole into place, poking the tip just over the branch that is to hold the rope.

Let the weight fall slowly to the ground; voila! The thin rope is exactly where you want it.

A thick rope is then pulled up in its place.

NOBODY will call the cops, though they might call the funny farm.

"Rick's out there fishing in one of his trees again!" (hi)

I also have a very large step ladder.

I can get up about 8' on it. So I can almost get a line 50' into the tree using this system.

With my EZ-Hang, I shoot up at a high angle, just when the weight is over the tree, I activate the brake with my thumb.

The once the weight has fallen a little, I carefully control its slow decent with my thumb.

No danger at all, unless the line breaks ☐ in which case . . . ring the bell and run like .ah get out!

Hi Rick,

The trees are linden trees, about 30' high, but with good spreads and they're probably 40' apart with the canopy limbs bumping into each other. Sooo, we're trying to go up 30', then horizontal probably 60-70' and then down.

The method you describe we were just talking about tonight! One of the guys said they saw the City with a hot stick reaching up and turning some switches off on a pole and wondered if long poles couldn't be used here too. The idea was shelved though as long fiberglass poles are expensive and they probably wouldn't be used much.

In the end, we've decided to try the simple manual valve actuated shooter. Judging from the videos on YouTube our shot isn't that hard of one, so it shouldn't take much.

It's amazing how one can get carried away with these things though, troll the net, there are ones made out of metal, multiple electric valves, aiming systems, etc..

We're thinking a cap with an air chuck. No need fpr an air gauge, we'll fill it from a portable compressor with a gauge. The cap on a larger pvc pipe air reservoir, a reducer to a valve, valve to barrel. Two caps and a short section of smaller pipe for a sabo to pull the line. Shouldn't cost much. May be less accurate than one you can hold like a gun, aim and fire electrically, but accuracy isn't the goal here, we're not aiming to go over a branch, we're aiming to go over two whole trees.

I'll update as we play!

Yeah, one of the web sites I visited that sells kits and complete units pointed that out too, their unit flies well, but no faster than if it were hit by a good player with a racket. I have no doubt the tennis ball units are the safest, they're just larger and more expensive to build. What we're looking at is smaller and using a small pvc sabo to pull the string, not as safe as a tennis ball, but I think still much safer than a hunk of lead.

There must be technique to it too Evan. If you read on the net you'll find some people love their EZ shooters and some, like us, find they don't work well at all.

The one telling thing is that when you read the reviews for the EZ Hang you'll find several mention switching to pneumatic shooters, but when you read up on the pneumatic shooters I've not seen one instance where people switched from them back to any other methods, indeed I've not read one review where anyone wasn't happy with their pneumatic shooter. I think that says a lot.

Can it be done other ways? Obviously it can. What method does everyone seem the happiest with? It seems it's the pneumatic ones, so we're going with the majority and seeing how it works.

If it doesn't work then we do have access to a 35' extension ladder, we may try that, though the fiberglass extension pole method isn't out of the running either...and of all those mentioned, is probably the only one that is permissible under most city codes.

Fun discussion guys! I knew we weren't the only ones to have faced this issue, it's great to hear how others have cracked this nut!

When I first got my EZ-Hang, I thought it was cr@p.
The darn weight just didn't go where I wanted it to.
After a bit of practice (say, 20 or 30 shots), I got the "hang" of it (Pun intended).
Now I can put it just about anywhere I want.

What I had to do was learn to aim way above where I wanted it to go, and then at the right time, push the brake with my thumb to interrupt its flight.

I suspect those unhappy with it, used it once or twice and didn't like.
I'm quite pleased with mine.

But for 30 ft.? Honestly I would buy a baseball or softball, drill a hole in it, screw an eyebolt into it and "sling" it over the tree.
Notice I said "sling", not "throw".
I'm no good at slinging either but with a little patience and 10 to 15 slings, it eventually goes where it is supposed to.
The entire investment is about $3.

SLING: grab the line about 18" above the ball and ling it round and round. I prefer slinging it under-arm. The trick is to let it go at the right instant.

>>> Hans, you attachment did not come through.

We got annoyed enough with the slingshot that we're not looking back.

Now, slinging a tennis ball...probably not as accurate as an air launcher, but....our neighbor has one of these for their dog and they chuck a tennis ball like no other....I may have to go visiting, with some dog treats and new tennis balls!

A good slingshot and some leads ... costs aehem ... I have no idea ...maybe 30 40 bucks?!? ...

Anything that will get you to a usable height above 30 feet will cost 30- 50 bucks (maybe more)

Tennis ball launcher

Fishing pole with weight

Used tennis racket with ball

Slingshot

Bow and arrow or crossbow

Etc etc.

Each of them has costs in the same range (more or less)

So ... what I did is ... I have seen nearly similar costs

Different performance ... and different safety

And then I selected the tennis ball launcher to have best performance, easy to use, and has highest safety (cause I also use that on fieldday)

Except the tennis racket and the fishing rod ALL OF THESE THINGS ARE FORBIDDEN HERE ...

(another reason why I took my homebrewed tennis launcher to be very save)

I am thinking that it will not be counted as a real weapon cause it is built with exact the performance that needed for a tree ... but save enough that even if you would have a direct hit you would have no injury (it will hurt somewhat and a "blue spot" ... but that□s all)

.... and when I do not use it for antennas ... then I play with the dog :-)

That can not be well done with the other possible solutions (except again the tennis racket) ...

I have MUCH FUN WITH THE DOG AND THE TENNIS BALL LAUNCHER ... GRIN

Over 2 trees or over one spezial branch (or close to an area in a tree) are
2 completely different things

I also use the launcher for retrieving weather sondes from trees

(I am a sonde hunter also)

We tried a slingshot (and still use it for lower heights) ... but there is a
height that is just tooo much for slingshot with a line and weight...

And that IS THE HEIGHT WHERE A LAUNCHER JUST STARTS TO WORK WELL :-)

The most recent pricing there is from 2013 and they said:

Pricing:
NEW PRICING: WOW! And you though gasoline was the only thing that has doubled in price in the last few years. To continue bringing you these outstanding surplus aluminum sections, we now have to compete directly with others who recognize the value of the high quality aluminum available in these items. We try to maintain a decent supply of pieces in stock; however, we are not sure how much longer these will be readily available.

Prices vary (from $9.00 to $12.00 each) due to the condition of the tube sections and the erratic availability of these through surplus outlets. Since our standard shipping boxes are suitable for quantities of 4 or 10, please keep that in mind when requesting quotes. Buyer pays all shipping costs.

Sooo. $108 to $144 plus shipping....The Rohn H-50 is $130 and I could drive to pick it up for about the same as the shipping cost of the military mast, soooo not really a bargain.

These ARE available -> they're just not available inexpensively any more.

My fault, I took too long to mend my errant ways and come back to amateur radio, so I missed some bargains!

4797. This odd multi band doublet

Yahoo group: SkyWires
Date: 2015-06-16 21:10:38 UTC
From: kd1ia
Topic: 4797 Message: 4797

Hi all and thanks for reading. I am currentlyantennaless and have a mind to work on that and get back on the air a bit. The good news is I have a 100ft plus tree next to water to hang my doublet from. I would like you who have the software and are willing to help to tell me what I might get by installing the following 4 wire sides fed to a manual tuner with open wire line. The legs are as follows

A: 124.8/124.8
A' 62.4 /62.4
B: 88.7 / 88.7
B' 44.6 / 44.6

These represent a half wave on 160 and 75 followed by
.64 wave elements on 40 and 20m.

Again this will be at apx 100ft fed with 450ohm line back to the tuner at the shack.

Any comments suggestions welcome!

Thanks for any help and I hope to be back on the air for the comming contest season doing the best I can.

Yep, I've read many such accounts on the net...one local said they were $35 for 12 at the hamfest in Lincoln just a year ago, this last March they were $75 at the hamfest.

The supply has evidently dried up and it seems everyone who has them loves them and aren't giving them up!

Oh well, I'll plod on. In the mean time, I'm still making contacts with my low loop...

We discussed that. He's flown his a lot and has done this before! He said as long as the wind was good it'll be fine. He also has two so will bring back up!

Interesting solution to the problem, though it won't put a wire over a specific branch like other methods. It'll get a wire over the whole tree though!

Interesting where this hobby of ours takes us!

Current is what radiates

Feed it high

A slight tilt does not hurt on 2 lowest bands ... but would show some front to back ratio (from high towards low) on next harmonics

Topic: 4802 Message: 4807

OK, THEN feed it high.

There are other factors, so just saying feed it high might not always be correct.

For instance, if the antenna’s main use is high band DX, its strongest lobe will be in the corner opposite the feedpoint, assuming it is approximately square. In that case, if there is not too much difference in height, then it should be fed with the opposite corner in the main direction of radiation.

However with so much difference in height, then it is best to take the high point.

If we use it I'll see if we can!

We decided to try the pneumatic shooter first.

Since I'm off work recovering and bored to death, and this isn't a precision project requiring good vision, I built the launcher yesterday.

I varied from the design in the link I posted a bit, here's what/why I did:

The object here is to get the wire over the trees, it's not to build a portable device that can be backpacked, etc. so simple, which also lends to inexpensive, won out over compact.

*) 1-1/4" sch 40 PVC was chosen. Make sure it has a pressure rating written on it. Pipe for use as Drain Waste Vent use only is sometimes sold and it's not pressure rated. Pressure rated pipe can be used as DWV though, so most hardware stores usually just carry pressure rated pipe, but it may be also be labeled as DWV. Bottom line, look for a pressure rating written on the side, if there is one it's good to use.

*) 1-1/4" was chosen because it's easy to make the projectiles for that size. Short 3" pieces of 3/4" pvc pipe with end caps glued on fit PERFECTLY in 1-1/4" pipe. A small wood screw thread eye hole screw was screwed into one end of each projectile for the string to hook to.

*) Most of the launcher designs on the net opt for good enough performance balanced with a small size. Because of this they tend to short the size of the air chamber. Reading the pneumatic tater tosser web sites (there's been a surprising amount of research on these things, they seem to be a favorite for science classes to figure out the best barrel lengths, air tank volumes, pressure, etc.), it seems the air chamber needs to be twice to four times the volume of the barrel, so we chose to go with twice.

*) Though compact wasn't a design criteria, neither is unwieldy either, so we wanted to balance the barrel length with the air chamber length. Looking at the tater tosser web sites, it seems two foot, though not optimum, works well.

*) With a two foot barrel we need four feet for an air chamber if we use the same size pipe, which we did to save money as the pipe is sold in 10' lengths usually (ACE Hardware actually sells it by the foot here, but it's more expensive that way. Still, if you wanted to shorten it up you could buy a short length of larger diameter and probably come out ahead).

*) This seems to work well. 6' is kind of long, but not bad. The 4' air chamber puts the valve at what feels like a convenient spot about waist high.

*) We opted for a manual valve. Electric valves work better, no doubt, but add to the cost of the project and judging from the YouTube videos and science class project data on the net, should give us the performance we need for our short hop.

*) We chose a 1" valve. Why? Because that's what everyone else chose! I think that's because it's a common size for an inexpensive sprinkler system dump valve. All the data on the net seems based on this size, and it was a bit less expensive than a 1-1/4" so we couldn't see any reason to not follow the herd.

OK, here's how it's built, I'll try to take pics later.

1-1/4" cap with valve stem installed in it.
4' piece of straight pipe.
1-1/4" glue to 1" threaded adapter.
1" threaded plastic ball valve.
1-1/4" glue to 1" threaded adapter.
2' piece of straight pipe.

Projectiles as described earlier.

6' feels good, it lets you brace it on the ground and angle to shoot it, the valve feels like it's in a good position. The valve stem will stick in the dirt during use though, so be mindful of that and always put the cap back on after charging.

We were hoping to play later today, but it's raining today, so it may be a day or two, I'll post back how it goes.

4810. Steve's Low Loop Resonance Test Results

Yahoo group: SkyWires
Date: 2015-06-19 01:17:59 UTC
From: slr_65@...
Topic: 4810 Message: 4810

Hi Guys,

My buddy dug up the 4:1 current balun so I played with it today and thought I'd share the test results.

My loop is approximately 210' ran at about 12' under the eaves of our single story ranch style house. It's about a 2' over hang and it's ran down the middle so it's about 12" from the wall and 12" from metal rain gutters. It's fed with about 35' of 450 ladder line to a ladder loc center insulator.

I had been running it through a Dentron Super Tuner with a 4:1 voltage balun and it will load 80 through 10 meter.

I have an MFJ-209 SWR analyzer with a frequency counter, but until today I had no way to find where it was resonant because I didn't have a stand alone balun.

I had hoped the stand alone blun would let the Kenwood tuner tune the loop, but no joy. It will tune 15 through half of 6 meter though.

If I tune the Dentron for 80 meter and leave it set for 80 meter the Kenwood will match it from to 30 meter though, so 20 is the only pain in the butt.

Anyway, with the stand alone balun I was able to use the MFJ to see where the low SWRs were at.

1005/210 is 4.78 so I figured that was one low SWR spot. It's a little off, but there's a lot going on here with the low height, proximity to a building, etc..

Onwards to the data....There were some places where it got lower (well, wasn't pegged above 4:1 as hard!), but these are where it significantly dips.

5.6 mhz 3.0:1
9.9 mhz 2.7:1
15.7 mhz 1.7:1
19.5 mhz 2:0:1
25.5 mhz 1.0:1
29.6 mhz 1.3:1

It looks like about every 5 mhz the SWR reduces. Interesting.

I left the current balun hooked up for now, though I'd see if there's any improvement in receiving or transmitting that's noticed.

My buddy has an MFJ combination 1:1 and 4:1 balun somewhere he's going to dig up, it'd be interesting to see what changing to a 1:1 balun does.

Also, I moved my radio room so that's why the ladder line has a long run. I could relocate the feed point and shorten the ladder line to something less than 20' if it would make a

difference.

Anyway, there's the results of the playing...I'd love to hear any thoughts, comments, etc..

FUN STUFF! 8-)

Hmmm, just thinking out loud, the SWR reduces about every 5hz,with is about where it starts dipping the SWRs and is near where it's predicted to be resonant. As the frequency comes up the SWR dips get better...is that due to ground proximity and as we get more wavelengths above the ground the better it behaves?

Steve,

Without some experimentation, it is difficult (dare I say impossible?) to know conclusively the reasons for your findings. But let me say here are some candidate reasons: ground proximity/conductivity, capacitive coupling to the house structure and/or contents, feedline attributes, balun attributes, system losses, etc. etc.

The antenna is so low, even on the highest bands, I'm not sure it is high enough to think in terms of "wavelengths above ground". Too, I tend to look at parameters other than SWR. Many very lossy antennas exhibit excellent SWR across broad ranges of frequency, yet are poor radiators.

Just some wild thoughts...

73,

Evan, K9SQG

Absolutely Evan, there's a whole lot (wrong) going on here! It's hard to pin any one thing down, and in fact there probably isn't any one thing, it's probably a mix of all you mentioned.

Shrug, it's working, I just gotta use the Dentron on some bands and takes a little setup, I can deal with that.

I gotta figure a way to get it away from the house at least though, higher would even be better.

My son had a thought, he has some scrap 2x4s, his thought was to cut them in half and make some 4'x4' 90s and screw them under the eaves, they'd come out a couple foot past the rain gutters and then up 4'. Not really a height gain, but an away from structure a bit more gain, but is it enough....enough to want to explain to the XYL why the top of her house looks like a prison's razor wire?! LOL!

DUMP THE 4:1 VOLTAGE BALUN!

BEST is to use a 1:1 Current balun at the tuner.
BEST here is a Balun Designs Model 1115t
www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/

The worst thing you can do with a tuner is put a 4:1 balun in front of it.
ALWAYS USE A 1:1 BALUN.

If you don’t have one handy but happen to have some unused coax, then you can easily make one.
Just wrap 22 or 23 ft. of RG-213 or RG-58 onto about a 4” form (i.e. PVC pipe).
It is OK to close space it (touching turns) but a little better if you space the turns with nylon rope (1/4").

You will see a picture of one in action in the last picture of the gallery of my QTH in Oklahoma:
http://www.dj0ip.de/my-station/oklahoma-2010/

Use this with your Denton Super tuner. It will work just fine.

It is an unfortunate myth that tuners need a 4:1 balun.
See: http://karinya.net/g3txq/tuner_balun/
Even the ATU manufacturers had this wrong for many years, but finally they figured it out and for the past 5 years or so, are now delivering their high power tuners with 1:1 Guanella baluns. No more 4:1.

Hang a bird feeder on it. That’ll keep the XYL happy.

The further away from the house, the better!

Even moving it horizontally might help.

Try to get the feedpoint at least 5 ft. away from the house.

Random thoughts here. I haven't been following these threads lately, so I don't know how much background info I have missed.

SWR itself doesn't indicate resonance. Nor does it necessarily relate to things like ground proximity. It is nothing but a half-blind measure of impedance.

Your antenna (with feedline) has some impedance at every frequency. If you plot it on a Smith chart, it usually makes loops and spirals that wander around on the graph. On an ordinary impedance vs. frequency plot, the impedance wavers up and down, a little like a damped distorted sine wave.

A dip in SWR means nothing more than the impedance curve getting closer to the middle of the Smith chart = the measurement impedance. With a good 4:1 balun, that impedance, at the output of the balun, would be 200 ohms. So if the antenna's impedance varies from say 100 to 1000 ohms (at the inside end of your feedline), every so often it passes closer to 200 ohms, and when it does, the SWR dips at that point. That's all it means, nothing more.

It's quite possible to make it so that the SWR dips nowhere near resonance, and is high at resonance.

For it to be resonant, it needs to have jX=0. But you are looking into the feedline, not just the antenna, so you won't see jX=0 at the same frequencies. The feedline essentially detunes the antenna and effective resonant points (as seen by your meter indoors) shift to new frequencies.

The only point in your SWR measurements that also indicates resonance, is when SWR=1.0:1, because that's the only one where we know X=0. (X=0 is necessary for SWR=1.0:1, but not vice-versa.)

"As the frequency comes up, the SWR dips get better." There is no particular reason for that. It just means the impedance is coming closer to 200 ohms (at output of balun). Might be because of losses, might be simply because that's what happens to happen.

The feedpoint impedance of large loops tends to waver above and below something (around 150 ohms, or was it 377 ?) as you go up and up in frequency, and it might happen to be getting closer to 200 ohms as a result.

Or consider that maybe the 4:1 balun isn't perfect. None of them are. Its increasing losses at higher frequencies could even be making the SWR dips look better, having nothing to do with what the antenna does.

Mounting an antenna low TENDS to increase its losses because of ground proximity (which isn't necessarily a horrible thing, in moderation) ...

which TENDS to reduce the impedance excursions between high and low.
Whether or not that reduces your SWR, or actually increases it, depends on
other factors.

Andy

FYI, there are some people who intentionally use very low antennas even on the lowest HF frequencies.

By low, I mean around 6 feet above earth, on 80/75 meters or 40 meters. At that height, they are a small fraction of a wavelength above earth, and tend to make fair-to-good NVIS antennas on those lower HF frequencies. Word is that such low antennas might help reject man-made noise, making them quieter. They do sacrifice efficiency, but some users of those antennas find that they "get out" well enough so efficiency is not that bad. Your mileage may vary.

One version (the "super gain NVIS antenna") has a 6-8 foot high folded dipole above either one or three wire reflectors laying on the ground.

The same idea might work for loops too.

Andy

Lots to digest guys, thanks!

Actually Andy, I DO get out fairly well for 80 meter. When I was a kid doing this we had a Yaesu 101E, but it didn't have the 80 meter crystals in it for some reason. Once I returned I knew I wanted 40 through 10, but wasn't too concerned with 80, I'd always heard it was very noisey, to the point of unusable in the summer. I just tuned up on it once to see if I could...and I could. Then I got to listening to it, it's actually quieter for me than 40 and it's fairly full of guys from Texas, Oklahoma, Kansas, Missouri, Iowa, and Illinoise for me (I'm in southeast Nebraska). Nice guys who don't mind my low signal (it's low, but stable they usually say), so it's become a favored band for me.

Andy, that is a myth. Antennas that close to the ground are worse than when they are higher, at least on TX.

A dipole or loop at a quarter wavelength will work better (on transmit) for NVIS than when mounted close to the ground for the reason you mentioned in your previous post: ground losses.

Once you go higher than 1/4 wavelength, that's when the NVIS efficiency drops off.

However your point about receiving quieter (i.e. less noise), might sometimes be true.

You had lots of good points in your previous post, but I would dump the 4:1 balun and only use a 1:1 Guanella. Much better CMI, thus less common mode current problem. The balun's primary job is to keep the common mode current out. Let the matchbox do the matching. If the matchbox can't match up to 200 Ohms, then the Op has bought a lemon. (hi)

The loop is close to 150 Ohms on upper bands, but it also depends on height, as I'm sure you well know.

Cheers!

We did play with the shooter tonight and we're almost there!

The thing will definitely chuck the puck over the trees!

Our problem is the string. On the first shot we laid it out on the grass and it pulled off the mark. On the second we put the string in a bucket and tried to loosely coil it, it was sailing fine, right on target but then a big mouse nest of string came out and grabbed a low branch, so just made one tree.

It was getting dark so we stopped. We dug up an open face fishing reel, it's getting duct taped on tomorrow!

Yeah, I think so too...it was working swimingly, it's just the string getting in the way, coming off a reel should be fine....we'll know tomorrow!

I just bought one.
Be aware that it comes naked.
You have to buy a battery set, which cost me another 30 bucks.
The battery connection for the internal wires is a piece of twinlead (zip cord) wire, cut flush.
You have to solder the batteries in.

Then you have to build 3 dummy loads to calibrate it before using.
This is really Simple Simon, “if” you have a good assortment of resistors – which I did.
I solder each of my resistors onto/into an RCA Phono Plug and will simply plug them into the analyzer through an adapter from PL to Phono.

However Sigi has one and he swears by it and I trust his judgment.
I haven’t had time to work with it yet and won’t for another 2 weeks.
We have a big Hamfest here in Europe next week and I’m busy preparing for it.

Normally I don't recommend stuff without trying it myself first, but in this case I trust Sigi enough to rely on his judgment.

I also have an MFJ-259B as well as a RigExpert AA54 scanning analyzer.
So I have a good pair to compare it too, if I ever find the time.

I hate to support China, but sometimes you just have to.

I wanted to build one of the Aussie Antenna Analyzer kits, but I don't think that's in the cards with my vision now.

If I'm going to antenna play though, it'd be nice to have some way to test half way decently. Doing a little research I found the Mini60 SARK100 seems to be well reviewed and a good buy.

Here's one review:

Topic: 4822 Message: 4825

Sark100 is a good analyzer (if you just need shortwave up to 6m)

I bought a sark100 and added a Bluetooth module (hc06) to it

Now I can measure swr direct at the antenna without the need for a long usb cable (in fact I can pull my analyzer up the pole or in the tree with the antenna and have NO cable at all ... so any influences of coax or ladderline is out of the test setup

Dig trough evilbay and you should find a sark for around 70-80 bucks

Sometimes they sell them for 25 bucks (BUT ADD 100 for postage!!!!) ....so carefully read the offers in evilbay

The mini60 is nearly the same analyzer ... only difference is that it has a lipo charger (sark100 has nimh charger) and it is a bit smaller

Dg9bfc

Sigi

Ps any questions?? Feel free to ask :-)

Put a 20' mast on each corner of the house. Either get some chainlink fence toprail which comes in 21' lengths?) or take two 10' pieces of conduit (EMT) that slip inside each other (1-1/4 and 1-1/2") and splice them together. If nothing else, drive a metal fence post (t-post) or a piece of heavy angle iron into the ground and tie the masts to them.

Significantly changing the length of the open wire feed will significantly change the feed impedance. Your feedline is a impedance transformer, the value varies with it's wavelength.

I think it depends on the impedance. Some antennas/feedlines need a
1:1, some need a 4:1, and some need no balun.

I have done experimenting here and some antennas/feedlines tune better
with a 4:1 balun, some with a 1:1.

Well, it depends. Whether a voltage balun or current balun is appropriate, and whether the ratio is 1:1, 4:1, 9:1, depends on the antenna and the bands of interest. Without knowing the parameters of the antenna SYSTEM, the complete system including feedline, it is impossible to select the best balun to use, although one might guess right. Whether that guess is correct for all bands of interest is an unanswered question. Often, it boils down to, "no single balun will be best for all of the bands of interest for the respective antenna" and then it becomes a matter of having more than one balun, more than one tuner, more than one antenna, etc. etc. For my operations, I've found the Johnson KW Matchbox works great, and it has NO balun; no it is not designed for impedances much below 50 ohms (resistive component) but my horizontal loops are above that for the bands I work. No balun to saturate, beefy components used, etc. so it is the best tuner for me BUT not necessarily for others. Hence, one can make an informed decision, or guess your way through experimentation; sometimes I use a blend of both, hi hi.

Subject: RE: [SkyWires] Steve's Low Loop Resonance Test Results

DUMP THE 4:1 VOLTAGE BALUN!

BEST is to use a 1:1 Current balun at the tuner.
BEST here is a Balun Designs Model 1115t
www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/

The worst thing you can do with a tuner is put a 4:1 balun in front of it.
ALWAYS USE A 1:1 BALUN.

If you don’t have one handy but happen to have some unused coax, then you can easily make one.
Just wrap 22 or 23 ft. of RG-213 or RG-58 onto about a 4” form (i.e. PVC pipe).
It is OK to close space it (touching turns) but a little better if you space the turns with nylon rope (1/4").

You will see a picture of one in action in the last picture of the gallery of my QTH in Oklahoma:
http://www.dj0ip.de/my-station/oklahoma-2010/

Use this with your Denton Super tuner. It will work just fine.

It is an unfortunate myth that tuners need a 4:1 balun.
See: http://karinya.net/g3txq/tuner_balun/

Even the ATU manufacturers had this wrong for many years, but finally they figured it out and for the past 5 years or so, are now delivering their high power tuners with 1:1 Guanella baluns. No more 4:1.

Subject: [SkyWires] Steve's Low Loop Resonance Test Results

Hi Guys,

My buddy dug up the 4:1 current balun so I played with it today and thought I'd share the test results.

My loop is approximately 210' ran at about 12' under the eaves of our single story ranch style house. It's about a 2' over hang and it's ran down the middle so it's about 12" from the wall and 12" from metal rain gutters. It's fed with about 35' of 450 ladder line to a ladder loc center insulator.

I had been running it through a Dentron Super Tuner with a 4:1 voltage balun and it will load 80 through 10 meter.

I have an MFJ-209 SWR analyzer with a frequency counter, but until today I had no way to find where it was resonant because I didn't have a stand alone balun.

I had hoped the stand alone blun would let the Kenwood tuner tune the loop, but no joy. It will tune 15 through half of 6 meter though.

If I tune the Dentron for 80 meter and leave it set for 80 meter the Kenwood will match it from to 30 meter though, so 20 is the only pain in the butt.

Anyway, with the stand alone balun I was able to use the MFJ to see where the low SWRs were at.

1005/210 is 4.78 so I figured that was one low SWR spot. It's a little off, but there's a lot going on here with the low height, proximity to a building, etc..

Onwards to the data....There were some places where it got lower (well, wasn't pegged above 4:1 as hard!), but these are where it significantly dips.

5.6 mhz 3.0:1
9.9 mhz 2.7:1
15.7 mhz 1.7:1
19.5 mhz 2:0:1
25.5 mhz 1.0:1
29.6 mhz 1.3:1

It looks like about every 5 mhz the SWR reduces. Interesting.

I left the current balun hooked up for now, though I'd see if there's any improvement in receiving or transmitting that's noticed.

My buddy has an MFJ combination 1:1 and 4:1 balun somewhere he's going to dig up, it'd be interesting to see what changing to a 1:1 balun does.

Also, I moved my radio room so that's why the ladder line has a long run. I could relocate the feed point and shorten the ladder line to something less than 20' if it would make a difference.

Anyway, there's the results of the playing...I'd love to hear any thoughts, comments, etc..

FUN STUFF! 8-)

Ken, the purpose of the balun is not to match the antenna.
By definition a balun's main purpose is to prevent anything going on in the antenna from unbalancing the inherent balanced flow of current in the feedline, be it openwire or coax.

The 4:1 current balun does a fair job at this as long as it is well matched.
As the SWR begins to go up, its CMI drops rapidly.
In contrast, the 1:1 current balun continues to do its job, even in the presence of higher SWR.

When we use a balun in an OCFD antenna, the impedance on all bands is between 200 and 400 Ohms and we can safely use a 4:1 current balun there. But in front of a tuner, we don't want to limit the matching range of the tuner, so a 1:1 balun is better.

When I say limit the matching range, I mean matching without incurring problems with common mode current, not just impedance matching. The 4:1 balun is going to begin to give you trouble above 200 to 300 Ohms and below 100 Ohms. It will play nicely in the middle

If all you do is run 100w into longer antennas, you will probably never have a problem and not believe what I wrote above.
But if you run 1kW and especially when you are trying to match a somewhat short antenna on a low band, you will quickly remember my words the first time you get bitten by the common mode current! (hi)

With 100w, generally the situation is such that we can get away with bending the rules.
But above 500w things begin to get touchy.

If you matchbox is not capable of matching the antenna's impedance without a 4:1 balun, then you have chosen the wrong matchbox for the job. End of story. There are plenty of matchboxes that match up to 2 or 3 kOhm or more, but there are just as many which do not.

With QRP, you can almost get away with murder! It really doesn't matter how you match it.

If I can help it, I make no exception to the rule: ALWAYS USE A 1:1 CURRENT BALUN IN FRONT OF THE TUNER (if you need a balun at all).

Of course sometimes with portable operations I also bend the rules because that's all I happen to have that will match the impedande.. But that doesn't apply to running high power.

That's GREAT news, thanks Guys!

I got the mini - from what I read the Chinese SARKS 0f the larger original design sometimes had an oscillator problem, it literally had a wrong part in it and skewed a reading. It could easily be fixed, but I'm not up to it with my vision these days. This problem was reported a couple years ago and it seems they did fix it, but yet I've read enough recent reports of people getting the evidently an old stock one occasionally that I decided to not risk it for a few bucks savings, the Mini60 it seems has never suffered from this problem, it's basically the old unit with some new upgrades and never suffered from the problems of the older one.

Mine comes with a battery, but yeah - naked, you download the manual and software. From what I read though, it seems like a bargain. I paid $110 shipped from a seller I've bought a bunch of Arduino stuff from without ever a problem, well, I did have one but they shipped me a new one without having to run the old one at a ridiculous shipping cost, so I'm comfortable with them.

I don't have anything bluetooth, so I didn't worry about that....hmmm may be I do....My wife's tablet may be bluetooth, I know it's android. We'll see when it gets here, bluetooth can be added.

Anyway, THANKS for filling me in! It should be here the first part of July, I'll play then....nice to know where to ask questions!

Hi Ken,

Yeah, I think four posts is going to be the ultimate answer, I'm thinking four Rohn H-50s so I can go 30' guyless. It's expensive, but not terrible and it's portable so if we have to move I can take 'em with me and maybe do something at the new QTH so no money left behind in the worst case scenario.

I"m taking high dose steroids right now and having some significant side effects lately, so just haven't been up tomuch beyond some minor playing with the balun and the air launcher with my buddy. I'll get back to my antenna issues soon...I talked to a couple neighbors, a couple have kids with those portable basketball goals, I'm wondering if I set two of those out in the yard and ran the loop on only one side of the house and then the other 3 over open, albeit low, ground if we can get away from some of the house effect problems? If it significantly makes a difference then I may see about getting a couple posts out in the yard rather than just going above the house. Some time rolling basketballgoals and a little time running some wire and we'll know....and yeah, I have incredibly GREAT neighbors!

Hi Rick,

I'm trying to get the Kenwood's tuner to work as automatic tuning would be nicer than manual for me with low vision, though I CAN do it.

The Kenwood says it wants 10 to 150 ohms, so it's evidently not overly robust, which I figured anyway as it clicks relays away probably switching fixed inductors and caps, where as the Dentron has a fixed inductor but BIG adjustable caps.

My buddy has a low power, 300 watt I think, 1 and 4 to 1 balun somewhere from his qrp camping days, he's going to try and dig it up and we'll see what it does, if for nothing else than entertainment value while I'm sitting here in recovery bored out of my mind.

I picked up you said sometimes you don't need a balun at all, how do I get from ladder line into the tuner then, the balanced line feeds go through the internal balun. Rather than open the unit to patch in, maybe just jerry rig a coax connector to open line and see what happens?

All in all, the Dentron is working fine....using the interal balun I can tune all bands without issue, with the current balun I can also tune all bands without issue. The current balun does seem to have a wider tuning "sweet spot" though so the coarse settings of the dial numbers are usually close enough that I can just dial in, hit auto tune on the Kenwood and be good to go. I could do that on 20 and below with the voltage balun but on 80 and 40 either had to use the MFJ with freq counter to dial it in, or just brush the caps and trya couple times with the auto tune to get it working. The current balun seems happier with the coarse seetings. Actually, I can set it up for 80 and leave the Dentron and it will autotune 40, which it won't do with the internal balun.

Evan,

You got some good mixed with the bad there.
You have some good points but also described what people have mistakenly done for many years.

The Antenna Tuner manufacturers have learned their lesson and switched away from 4:1 baluns, now building 1:1 baluns into their tuners. They have learned, but most of the ham community is still behind the power curve on this point!

There is plenty of solid information available on this with mathematical proof, but also backed up by lab and field test data. Most of it is not written in any books, but it is on the web. Unfortunately there is more mis-information on the web about baluns than good information.

First of all, we need to understand what a balun is, what it does and that it is not a part of the antenna. One more time: the balun is not an antenna accessory! It is a transmission line accessory.
You will find baluns explained in the transmission line chapter of the ARRL Handbooks, not in the antenna chapter.

The best single source for reading about and understanding baluns is a paper written by Roy Lewallen, W7EL and published by the ARRL in the first issue if its series of "Antenna Compendium" books. The title is “Baluns, what they do and how they do it.”
http://www.eznec.com/Amateur/Articles/Baluns.pdf
You find it on the EZNEC web site because Roy is also the author of EZNEC.

When the balun is located at the antenna and when feeding with coax transmission line to the antenna’s feedpoint, then we consider the transformation ratio of the balun and choose appropriately.
We should ALWAYS choose a current and NEVER choose a voltage balun.

In cases where the antenna's feedpoint impedance is far off from that of the balun, we should actually use a device called a “hybrid balun” which has a 1:1 current balun on the TX side and a transformer of some ratio on the ANT side. The transformer may even be the same schematic of what we call a balun in other applications (yes, even the voltage balun works here), but if its impedance is not looking into a pretty good match, it won’t “bal”. Therefore it alone is not a balun; just a transformer, and we need the additional 1:1 balun in front of it to achieve the required amount CMI.

Even most balun manufacturers don't understand this point because most of them are copy cats, just building what the good manufacturers build, but a little cheaper. The good ones who understand the situation are Balun Designs and DX-Engineering - if you speak to the right person at DX-E. The balun portfolio of DX-Engineering was architected by Tom Rauch, W8JI, and most of what I know about baluns, I learned by studying his web pages. He also says to ALWAYS use a 1:1 balun in conjunction with an antenna tuner.

When using an antenna tuner, the impedance of the antenna system DOES NOT DETERMINE which balun to use. We should ALWAYS use a 1:1 balun here.

When using an antenna tuner, it is important to keep any common mode current OUT of the matchbox. A "4:1 voltage balun" will NEVER do that and a "4:1 current balun" will only do it over a limited impedance range. For feeding openwire, a 1:1 current balun is the best thing going (short of the Johnson Viking Matchbox) for this application.

If your matchbox doesn't have the range you need and you don't want to (or can't) buy one with a broader range, then place a 1:1 current balun directly at the matchbox and follow it with a 4:1 balun at the antenna side of the 1:1 balun. This will do the trick.

SIMPLY USING A 4:1 BALUN (alone) IS THE WRONG THING TO DO AND YOU WILL GET BURNED (physically) IF YOU DO THAT AND RUN HIGH POWER!

The Johnson matchbox of course was great. It is always best to use a truly symmetrical coupler when feeding with openwire feedline. By nature of its TX side and ANT side being galvanic-coupled instead of DC-coupled, we gain at least an additional 20 dB of CMI, which really helps keep out the nasty effects of common mode current.

BTW, the Johnson Viking Matchbox was the greatest thing going 50 years ago, but then we acquired the WARC bands. A German company called "Annecke" brought out an improved version of the JV Matchbox which was significantly better at matching these new bands than the old JV matchbox was, AND it had improved matching range.

All of this is described on my web site, as well as Upgrade Instructions on how to add the Annecke improvements to the older Johnson.
www.dj0ip.de/antenna-matchboxes/symmetrical-matchboxes/viking-vs-annecke/
and
www.dj0ip.de/antenna-matchboxes/symmetrical-matchboxes/j-viking-upgrade/

We [should] never stop learning, even when it means unlearning some of our mistakes of the past.

DUMP THE 4:1 VOLTAGE BALUN!

BEST is to use a 1:1 Current balun at the tuner.
BEST here is a Balun Designs Model 1115t
www.balundesigns.com/model-1171-1-1-atu-current-balun-1-5-54-mhz-5kw/

The worst thing you can do with a tuner is put a 4:1 balun in front of it.
ALWAYS USE A 1:1 BALUN.

If you don’t have one handy but happen to have some unused coax, then you can easily make one.
Just wrap 22 or 23 ft. of RG-213 or RG-58 onto about a 4” form (i.e. PVC pipe).
It is OK to close space it (touching turns) but a little better if you space the turns with nylon rope (1/4").

You will see a picture of one in action in the last picture of the gallery of my QTH in Oklahoma:
http://www.dj0ip.de/my-station/oklahoma-2010/

Use this with your Denton Super tuner. It will work just fine.

It is an unfortunate myth that tuners need a 4:1 balun.
See: http://karinya.net/g3txq/tuner_balun/
Even the ATU manufacturers had this wrong for many years, but finally they figured it out and for the past 5 years or so, are now delivering their high power tuners with 1:1 Guanella baluns. No more 4:1.

Subject: [SkyWires] Steve's Low Loop Resonance Test Results

Hi Guys,

My buddy dug up the 4:1 current balun so I played with it today and thought I'd share the test results.

My loop is approximately 210' ran at about 12' under the eaves of our single story ranch style house. It's about a 2' over hang and it's ran down the middle so it's about 12" from the wall and 12" from metal rain gutters. It's fed with about 35' of 450 ladder line to a ladder loc center insulator.

I had been running it through a Dentron Super Tuner with a 4:1 voltage balun and it will load 80 through 10 meter.

I have an MFJ-209 SWR analyzer with a frequency counter, but until today I had no way to find where it was resonant because I didn't have a stand alone balun.

I had hoped the stand alone blun would let the Kenwood tuner tune the loop, but no joy. It will tune 15 through half of 6 meter though.

If I tune the Dentron for 80 meter and leave it set for 80 meter the Kenwood will match it from to 30 meter though, so 20 is the only pain in the butt.

Anyway, with the stand alone balun I was able to use the MFJ to see where the low SWRs were at.

1005/210 is 4.78 so I figured that was one low SWR spot. It's a little off, but there's a lot going on here with the low height, proximity to a building, etc..

Onwards to the data....There were some places where it got lower (well, wasn't pegged above 4:1 as hard!), but these are where it significantly dips.

5.6 mhz 3.0:1
9.9 mhz 2.7:1
15.7 mhz 1.7:1
19.5 mhz 2:0:1
25.5 mhz 1.0:1
29.6 mhz 1.3:1

It looks like about every 5 mhz the SWR reduces. Interesting.

I left the current balun hooked up for now, though I'd see if there's any improvement in receiving or transmitting that's noticed.

My buddy has an MFJ combination 1:1 and 4:1 balun somewhere he's going to dig up, it'd be interesting to see what changing to a 1:1 balun does.

Also, I moved my radio room so that's why the ladder line has a long run. I could relocate the feed point and shorten the ladder line to something less than 20' if it would make a difference.

Anyway, there's the results of the playing...I'd love to hear any thoughts, comments, etc..

FUN STUFF! 8-)

Seve,

Unfortunately ATU’s built into our transceivers never have the tuning range of the external ones.
That would require several more coils and capacitors.
An ATU that only tunes to 150 Ohms is pretty useless for this kind of work and in my opinion, should better be called an antenna Pruner It just doesn’t have high enough matching range.

You can improve that with the use of an external transformer but I STRONGLY suggest placing a 1:1 Maxwell or even better Guanella choke between the Kenwood and the 4:1 transformer. A 4:1 balun serves just as a transformer in this application.

You may find on some bands it tunes best with the 4:1 in and on other bands it tunes best with it out.
When using the Dentron, always leave it OUT.

I also have little stick-on labels on my matchbox. These are pre-tune spots, making it easy and quick to change bands.

Good luck.

Subject: RE: [SkyWires] Steve's Low Loop Resonance Test Results

Hi Rick,

I'm trying to get the Kenwood's tuner to work as automatic tuning would be nicer than manual for me with low vision, though I CAN do it.

The Kenwood says it wants 10 to 150 ohms, so it's evidently not overly robust, which I figured anyway as it clicks relays away probably switching fixed inductors and caps, where as the Dentron has a fixed inductor but BIG adjustable caps.

My buddy has a low power, 300 watt I think, 1 and 4 to 1 balun somewhere from his qrp camping days, he's going to try and dig it up and we'll see what it does, if for nothing else than entertainment value while I'm sitting here in recovery bored out of my mind.

I picked up you said sometimes you don't need a balun at all, how do I get from ladder line into the tuner then, the balanced line feeds go through the internal balun. Rather than open the unit to patch in, maybe just jerry rig a coax connector to open line and see what happens?

All in all, the Dentron is working fine....using the interal balun I can tune all bands without issue, with the current balun I can also tune all bands without issue. The current balun does seem to have a wider tuning "sweet spot" though so the coarse settings of the dial numbers are usually close enough that I can just dial in, hit auto tune on the Kenwood and be good to go. I could do that on 20 and below with the voltage balun but on 80 and 40 either had to use the MFJ with freq counter to dial it in, or just brush the caps and trya couple times with the auto tune to get it working. The current balun seems happier with the coarse seetings. Actually, I can set it up for 80 and leave the Dentron and it will autotune 40, which it won't do with the internal balun.

I remember reading in an older antenna book (have to look to see which one) that the lower a loop antenna, the lower the impedance. And the longer in wavelengths the antenna is, the lower the takeoff angle. So by my reading of the text, wouldn't a 1550' loop at around 10 feet off the deck, be a fairly decent dx antenna? I downloaded some antenna software, but haven't been able to play with it to see how it would model out.

I've got a large loop up, that I haven't fully tested yet. It is quiet, for my area and powerline noise and it's kinda shaped like the state of Massachusetts with Cape Cod hacked off. Kinda like a L that is upside down and backwards. I plan on testing it out more on field day, but I'd be curious if anyone that is modeling software savvy could possibly model it quick like to give me more of a clue.

Thanks

That is only part of the story, Joel.

Besides takeoff angle and impedance, there is a third, important factor: ground losses.
When we get too close to the ground, ground losses go up.
This is true for all horizontal antennas.

10’ is even low for 20m, but for the higher bands, then it would be ok.
However the gain you are referring to is not omni-directional.
It is at 90 degree increments from the feedpoint (assuming nothing is physically influencing and disturbing the pattern)

30 to 40 ft. is actually a good compromise between giving us some nice lobes in these 4 directions, while still having enough radiation in between to work thos directions to, albeit with a somewhat weaker signal.

Hi Rick, yeah, I figured that, but some guys have had good luck with the 590 tuner, but I think they had a fairly resonant antenna to start with, my loop is just what fits.

Before I lost my vision I picked up another Dentron with the thought of using an Aruino micro and stepper motors to make a tuner....I may still, I'm looking for an Arduino IDE with high contrast I can see.

The balun I have is a Balun Designs, I dropped a note to them to see if this one could be converted to a 1:!, they said yes for avery reasonable charge, so I'm thinking I'll send it in to them (it's not really mine, but it's on permanent loan, was spare for my buddy - I showed him the thread here, he agrees swapping it for a 1:1 would make better use of it, even if it migrates back to him...he'll use it with his tuner if he ever needs one).

Thanks, I'm really enjoying this group!

Steve

Yes, your loop not being resonant on 80m means the impedances will be a bit different than what we usually see with a resonant loop. I honestly have no idea what they might be. Doesn’t really matter. That’s what we have (good) matchboxes for!

A few days ago a question was brought up about using different sizes wires on a antenna. No problem as long as it does not break it is OK and mixing sizes is no problem,
For a easy way to join wires and also keep it adjustable I always use split bolts.

http://i1102.photobucket.com/albums/g453/KD0ZZ/160%20Loop/SplitBolt_zps565c8c1e.jpg
For a standard dipole add them at the center insulator for a quick change
.http://i1102.photobucket.com/albums/g453/KD0ZZ/QuickChangeDipole008.jpg
Split bolts can be found at any hardware or big box home store. Simple, quick and no soldering iron needed in the field.

Rich, KdØzz

Hello Steve

You can add bt module also to the mini60 (cause it is actually the same design as the sark100 with just the charger changed and case made a bit smaller) ... if you wanna add bt ... then I can send you all needed details

Bt can be used on a tablet/smartphone with an adroid app ... or on the pc with windows software (if needed I can send both to you in direct mail)

Greetz

On page 2 of Everett's newly uploaded file, you will see his home-brew dual-core 4:1 Guanella balun.
Look carefully at the spacing between the two cores when they are soldered together.
THIS IS CORRECT.

The balun shown in the file referred to a couple of days ago, the one showing how to build a balun, had too narrow of spacing, or actually no spacing at all. This is probably the reason the SWR results of the narrow spaced toroid balun were less than optimum.

Also notice that he has inserted his enamel-insulated wires inside of Teflon insulation.
Everett used #16 wire which is certainly thick enough for this size of core.
In fact #18 or #20 would suffice because these cores are really only safe for about 500 or 600 Watts.

BTW, I use the same size cores in my main station antenna, an 80m OCFD, and I run 600w.

Rick,

Looks like you have found a new home here. Later I plan on writing a good detailed article on how to build a 4:1 Balun including where to get all of the parts. Lots of pictures.

I was looking Mouser's web site this morning and the carry a 61 mix core that is a little larger than the FT140-61. I may later order some to try out.

Although I don't show the sweep in the article that I posted it looks quite good on 6 and 2 meters. So I guess you could call it a 10 band antenna.

OK, more playing today since I have the stand alone bslun.

The doublet ladder line fine is cut to 40 meter but the Kenwood can't match it, it can't match until a higher band, I don't recall which.

I have a coax fed center insulator though, so I cut a coax fed 40 meter dipole and hung it exactly where the ladder line fed one was at.

The Kenwood can match 40, 17, 15 and 10!

With the Dentron I can of course match everything. I like 80 and 20 so I'll have to match them, but 40 and the rest are now automatic, that's progress!

The SWR sweep of the coax fed is interesting, not many SWR swings, most stay in the 3.5ish range, here's what I got:

7.0 mhz = 2.8:1 Kenwood matches
21.2 mhz = 1.0:!
35.2 mhz = 1.7:1

So, this leads us back to the 4:1 balun and low antenna...low lowers impedance and the balun is lowering it further, with more impedance by using coax my Kenwood is happier? I talked to one guy on 20 meter, said I sounded fine.

Again, fun stuff...I need to get off my butt and doing something!...hmmm, I should hook the ends of the dipole up to the loop and see what a coax fed loop does....

Steve

Thanks for the reply Rick.

So to minimize ground losses could one run an electric fence wire along the ground under the loop and then attach that to the grounding system somehow?

It should have less losses than using the chain link fence I would think.

I could insulate the return wire off the ground fairly easily actually.

I know it's like using an electric knife to cut butter, but the powerline noise is really bad in the summer months. Getting it any higher than the olive trees and you're looking at starting to interfere with the power lines that are on 2 sides of the property. I've got a 2 1/4 mile rolls of electrical fence wire. I might just try it to see how it will work. Do some testing before and after to see if there is a difference in received and transmitted signals. Hopefully I could get that done before field day.

Thanks again

OK, getting late for playing tonight, but for tomorrow night...

Usually 468/Freq gives the length you get the best match. So freq times length equals 468. Well, I've got so much going on with the low height, structure, etc. that the 468 constant isn't holding true. OK, well I have two of the three pieces to figure out the Casa Del KA0NEB constant don't I? Basically the new dipole is cut to 66' (I left some for trimming) and it's very happy at 21.2 mhz, so 66*21.1 gives us 1399.2 for the new constant. OK, if I want it to be happy around 7.2 then 1399.2 / 7.2 = 194.33 or 97.16 per leg? Of course I'm bending around the house so that may play in...anyway, on the right track here, all wet, or you need something to do anyway Steve, go play and report back?

OK, I took the reporting back option, and am skeeter bit to death for my effort!

But the answer is....yes, that does work, mostly.

I measured the loop, I was off, I thought the house was 65x30 with about 2' to be added for running in the middle of the eaves, but there's only 187' of wire in the loop.

I cut the loop in half and the low SWR point moved right where the modified formula predicted - just shy of 7.5 mhz. It lets the Kenwood tuner work on 40 fine though, and it works on every other higher band except of course, 20. What is it about 20 that makes it a pita? The SWR does dip a little above 20, but doesn't get below 3:1, which my Kenwood seems to need before it will tune. There are other dips in the higher harmonics and they dip much better than 20 does, what's the deal with that?

I need a little more length to move it down just a bit more, but I'm out of room looping the....since I'm doing everything I shouldn't already, I wonder if I could let them over lap each other on the eaves for a couple feet at the end?

Again, fun stuff. I can deal with this, if I can most on the Kenwood auto tuner and just use the Dentron for 80/20 that's fine. Though I'm liking 80 I don't use it much, so antenna switch and feed the Dentron through the Kenwood's second antenna input and leave the Dentron set there and then switch the antenna and let it feed the first antenna input to the Kenwood and let it's tuner handle those bands. It's doable.

It'll be interesting to see if the 1:! balun works as well as the coax seems to be. Also, I see sometimes guys use 75 ohm RG6 coax, possibly try it to see if the increase in imedance helps?

So many 'speriments....just what I need, something to keep me busy!

Well, 187 feet is 3 half waves at 7.5 MHz. So depending on where the feed point is along the wire, it may be high or low impedance on 40 meters.
On 20, actually 15 MHz as is, the antenna is 3 waves long. This may be causing a very high impedance which the tuner cannot handle.
Adding 10 feet of wire to the loop should put near 7.150. The wire could be just a half loop, which means it drops vertically 5 feet from one end of the loop,and then back up to the other end of the loop. That way you still have the same physical size loop but electrically it is longer.
Use a 3 to 6 inch insulator between the ends of the current loop. PVC water pipe should do. Then the added 10 feet can hang from the PVC.

Hi Don,

I tried the coax fed loop and though I could Dentron tune it, the Kenwood wasn't happy.

In that incarnation it's a rectangle and it's fed in the middle of the south long side.

I cut the loop in the middle and then the Kenwood is happy with everything but 20 meters.

I added 5' on to each end and let it dangle. 1:! at 7.2, but over 3 at 20, it gets happy around 17 mhz. Everything else close enough the Kenwood is happy.

20 is annoying me!

GM Everett,

If your pole can support the weight, you can use FT-240-61.
They're $19 ea. at www.spiderbeam.us and you can get them in single units there.
Some of the other sources I have found have minimum quantity restrictions.
I've also bought toroids on ebay.

In fact since you want to cover 80m as well, it would be even better to use -51 or -52 material.
These have a permeability about twice as high as -61, yet only half as much as #43.
This would give you a little higher CMI on 80m.

I'm interested in the results of your research.
People are always asking me where to buy this stuff in the states and I honestly don't know.
I know where to buy it here in Europe (Germany and UK), but no idea in the states.
I'm checked all the US ham radio stores that I am familiar with but can't find it.

Seems more people home-brew here in Europe than in the states because we have several stores that supply us with this stuff.
For instance DX-Wire. Www.dx-wire.de (you can change the language to English).

Rick,

Looks like you have found a new home here. Later I plan on writing a good detailed article on how to build a 4:1 Balun including where to get all of the parts. Lots of pictures.

I was looking Mouser's web site this morning and the carry a 61 mix core that is a little larger than the FT140-61. I may later order some to try out.

Although I don't show the sweep in the article that I posted it looks quite good on 6 and 2 meters. So I guess you could call it a 10 band antenna.

On page 2 of Everett’s newly uploaded file, you will see his home-brew dual-core 4:1 Guanella balun.
Look carefully at the spacing between the two cores when they are soldered together.
THIS IS CORRECT.

The balun shown in the file referred to a couple of days ago, the one showing how to build a balun, had too narrow of spacing, or actually no spacing at all. This is probably the reason the SWR results of the narrow spaced toroid balun were less than optimum.

Also notice that he has inserted his enamel-insulated wires inside of Teflon insulation.
Everett used #16 wire which is certainly thick enough for this size of core.
In fact #18 or #20 would suffice because these cores are really only safe for about 500 or 600 Watts.

BTW, I use the same size cores in my main station antenna, an 80m OCFD, and I run 600w.

That is not going to help, Joel.
That works great with quarter wave verticals.
Horizontal wires need HEIGHT.
There is no substitute for that, that I know of.

Thanks for the reply Rick.

So to minimize ground losses could one run an electric fence wire along the ground under the loop and then attach that to the grounding system somehow?

It should have less losses than using the chain link fence I would think.

I could insulate the return wire off the ground fairly easily actually.

I know it's like using an electric knife to cut butter, but the powerline noise is really bad in the summer months. Getting it any higher than the olive trees and you're looking at starting to interfere with the power lines that are on 2 sides of the property. I've got a 2 1/4 mile rolls of electrical fence wire. I might just try it to see how it will work. Do some testing before and after to see if there is a difference in received and transmitted signals. Hopefully I could get that done before field day.

Thanks again

That is only part of the story, Joel.

Besides takeoff angle and impedance, there is a third, important factor: ground losses.
When we get too close to the ground, ground losses go up.
This is true for all horizontal antennas.

10’ is even low for 20m, but for the higher bands, then it would be ok.
However the gain you are referring to is not omni-directional.
It is at 90 degree increments from the feedpoint (assuming nothing is physically influencing and disturbing the pattern)

30 to 40 ft. is actually a good compromise between giving us some nice lobes in these 4 directions, while still having enough radiation in between to work thos directions to,

albeit with a somewhat weaker signal.

CAREFUL STEVE! DON’T JUMP TO ANY FALSE CONCLUSIONS.

A good SWR * IS NOT ANY INDICATION AT ALL * of how good an antenna actually performs.
Lossy coax will tend to lower SWR peaks across the hf spectrum and wrongly show more broad banded dips.

I find it curious that your SWR is so bad on 40m and so good on 15m.
Normally it’s the other way around.
For me, lights go on when I see something like that. Something is wrong.

A statement like SWR is 2.5:1 is pretty useless information on its own.
What is needed is a scan of the SWR across the entire band, beginning about 100 kHz below and ending about 100 kHz above the band. If your analyzer doesn’t have a scanning feature, then simply measure it manually in 50 kHz steps and record the values.
This enables us to get a picture of how the antenna is behaving, then comparing to how we know an dipole should behave.

Before I had a scanning analyzer, I made myself Excel spreadsheets for each of the bands with Frequency in the first column and SWR in the second. Then using Excel’s features you can plot the curve. What it should look like is in any antenna book.
If it doesn’t look like this, there’s something rotten in Denmark!

I think you said you purchased a SARK Mini60.
That can scan the bands.

What you want to do is scan the entire hf spectrum, beginning just below the lowest band of the antenna, and then scan each ham band individually with a scan just wide enough to show about 100 kHz above and below the band. This gives a good snapshot of what the antenna is doing.

Subject: Re: [SkyWires] Steve's Low Loop Resonance Test Results

OK, more playing today since I have the stand alone bslun.

The doublet ladder line fine is cut to 40 meter but the Kenwood can't match it, it can't match until a higher band, I don't recall which.

I have a coax fed center insulator though, so I cut a coax fed 40 meter dipole and hung it exactly where the ladder line fed one was at.

The Kenwood can match 40, 17, 15 and 10!

With the Dentron I can of course match everything. I like 80 and 20 so I'll have to match them, but 40 and the rest are now automatic, that's progress!

The SWR sweep of the coax fed is interesting, not many SWR swings, most stay in the 3.5ish range, here's what I got:

7.0 mhz = 2.8:1 Kenwood matches
21.2 mhz = 1.0:!
35.2 mhz = 1.7:1

So, this leads us back to the 4:1 balun and low antenna...low lowers impedance and the balun is lowering it further, with more impedance by using coax my Kenwood is happier? I talked to one guy on 20 meter, said I sounded fine.

Again, fun stuff...I need to get off my butt and doing something!...hmmm, I should hook the ends of the dipole up to the loop and see what a coax fed loop does....

Steve

NOPE! That's all wrong.

These bands are not directly harmonically related like that.
You are forgetting one very important fact: "End Effect".

The formula for a dipole is 492/f. (in free space)
On earth, the velocity factor of the wire shortens the constant to about 482.
Then “End Effect” shortens the formula again from 482 to 468.
But this is only when you have just one half wavelength of wire.

On 15m you have 3 half wavelengths.
Only one is affected by end effect (the one made of the two outer ends).
So basically you wire length should be:

(482/f) + (482/f) + (468/f) . . .

where “f” is whatever frequency you want the 40m dipole to resonate on, on 15m.

You are going to come out with something like 69 or 70 ft.
Therefore a 66 or 67 ft. dipole is too short, thus 15m resonance will be too high.

But your 15m resonance is not too high, so there is something wrong here.

If it were in the clear, not bent, and working properly, then a dipole resonate at about 7.1 MHz is what you should shoot for.
This will make the 15m resonance about 21.6 MHz. However it is still well within the matching range of your matchbox and it will work just fine on both bands.

Also, the fact that the dipole bends and goes around a corner changes the picture, but I can’t say by how much.

It is a myth that antennas very low to the ground work better for NVIS than when they are higher up.

The radiation angle is the same for these antennas when they are close the ground as it is when they are ¼ wavelength in the air.

However the ground losses increase as we move it closer to the ground, and as we get real close, the ground losses shoot way up.

So a 80m dipole 15’ off of the ground is worse than one 40’ off of the ground in all cases, NVIS, DX, anything.

Although it might be quieter as far as noise goes.

However is you take the higher antenna and reduce your RF gain, or use an attenuator, it will be quieter too.

This is documented in any antenna book.

Check the vertical radiation pattern of any modeled dipole at various heights.

Cebik did a paper on this once. Perhaps I can find it. I’ll have to search my files.

I have a SARK on order, but it's a few weeks out as it's coming from China.

I have an MFJ-209 with an external frequency counter, but it's not calibrated above 3:1 and just coarsely below. The frequency adjust is pretty touchy too, so its not the best tool for detail work. If I get time I may try to do a better data compilation though.

I'm just trying to avoid the pita of manually tuning up every band change, it's not easy with low vision. The markings on the Dentron are coarse, sometimes they work, sometimes I gotta touch 'em up. I guess I could put a coax switch and put the analyzer in permanent with the flip of a switch, or maybe just printing a new scale for the front of the Dentron that's finer calibrated...what I'd like to do, but I can't see the Arduino IDE any more, is couple pots to the cap shafts and read them with the Arduino and then display a precsion number on a BIG display. I gotta find an Arduino IDE with high contrast fonts.

I may have a reprieve though, there are two trees in the city right of way that you usually can't touch (they fine people for trimming them!), I figured all they could do is say no, so I asked...I CAN hang a wire in them! 8-) So we may get some height yet!

Go an buy an autotuner (cg3000 or one of the sgc autotuners)

Put a choke (balun) on the input of the tuner (and also add chokes for the control and/or power cable) ... so the tuner is floating" (rf wise)

My friend andreas uses such a setup (ladderline fed doublet) with such a tuner and he can work all bands without touching any knob ... just qsy and transmit (and tuner does the rest

Your internal tuner can not do that (much smaller tuning range)

Using tuners in a row (the dentron and the internal tuner) is also not a good solutions (2 tuners = 2 times tuner loss)

4866. Steve's Analyzers and Matchboxes

Yahoo group: SkyWires

From: Rick - DJ0IP / NJ0IP
Topic: 4810 Message: 4866

Steve,

I changed the subject line.
We simply MUST start doing that every time we change the content of the email.

Under "Steve's Low Loop Resonance Test.."
We have had:
➢ Low Loop Resonance Test
➢ Different types of masts
➢ How to get a rope in the tree
➢ Details of sling shots
➢ Details of pump guns
➢ Baluns
➢ Shapes of loops
➢ Analyzers
➢ Matchboxes

That is totally inefficient.
It makes it impossible to look back on previous posts on a particular topic because you can't find the right one.
They all have the same subject line.

Now to the Analyzers:

The MJF-209 is not very effective but a lot better than no analyzer at all.
At least you don't have to use the transmitter for checking.

NEVER EVER LEAVE THE ANALYZER IN THE LINE VIA A SWITCH.
You will soon fry the analyzer!
Once you get your antenna pruned correctly and the Dentron marked correctly, it will be easier.

It will take a while to learn to use the SARK, but it is a good low cost means of really evaluating your antennas.

The matchbox solution is, you need to buy a new AutoTuner.
But buy a good one. All tuners were NOT created equally.
Some tune to just 600 Ohms, others to 1200 Ohms, most can match up to 1600 Ohms, and the very good ones can match up to 3200 Ohms.

I'm sure you will get a load of opinions on "which Autotuner", but my preference for a good, yet low cost tuner is the MFJ-991B. It is identical to the 993B, except it does not have the cross-needle watt meter. The 991B costs about $230 and the 993B costs $269.
These two tuners can match from 6-1600 Ohms at 300w or switchable to 6-3200 Ohms at 150w.

Either of these will give you the push-button matching you are looking for.
But before you begin, you really should have your antenna(s) as efficient as you can get

them under the circumstances.

Also, you must remember to always reduce power to something like 10 to 30 watts before activating the external tuner.

Your 40m dipole sure sounds suspicious to me!

I hope you can use those two trees.
I have never had any luck asking the city for permission to use anything, except their restrooms at the city hall.

Subject: RE: [SkyWires] Steve's Low Loop Resonance Test Results

I have a SARK on order, but it's a few weeks out as it's coming from China.

I have an MFJ-209 with an external frequency counter, but it's not calibrated above 3:1 and just coarsely below. The frequency adjust is pretty touchy too, so its not the best tool for detail work. If I get time I may try to do a better data compilation though.

I'm just trying to avoid the pita of manually tuning up every band change, it's not easy with low vision. The markings on the Dentron are coarse, sometimes they work, sometimes I gotta touch 'em up. I guess I could put a coax switch and put the analyzer in permanent with the flip of a switch, or maybe just printing a new scale for the front of the Dentron that's finer calibrated...what I'd like to do, but I can't see the Arduino IDE any more, is couple pots to the cap shafts and read them with the Arduino and then display a precsion number on a BIG display. I gotta find an Arduino IDE with high contrast fonts.

I may have a reprieve though, there are two trees in the city right of way that you usually can't touch (they fine people for trimming them!), I figured all they could do is say no, so I asked...I CAN hang a wire in them! 8-) So we may get some height yet!

Rick,

I put together a spread sheet listing the most common ferrite cores and their cost from various suppliers. I also have listed the companies web site addresses. I will post it here on this site later today.

If you are just looking for 1 or 2 toroids, then kit parts is the best place to go. The FT240-61 cores are $10 each and the FT140-61 cores are 2 for $5. If you are buying more than 1 or 2, than either Mosure, or Arrow are the place to go.

I will have to try the K, or 52 cores for a balun. The FT150K cores would make a nice 4:1 balun, but their cost is $8 each at CWS and I can get the FT240-52 cores for around the same price. I also found a place to get the 52 mix in FT140-52.

On Field Day we will be setting up a 40 meter Delta loop, which was tuned about a month ago when we set it up on a dry run. The over all length is 139' and the vertical sections are 41' long. I will sweep it using various baluns, 4:1, 2.5:1, 2.25:1 and 1:1 and write up a article showing the results. However, when doing a quick and dirty check the 2.5:1 was better than the 4:1 balun.

We are also going to put up a 160 meter Skywire loop, which will be 574' long. However, we plan on feeding it with ladder line and use a tuner. If I have time I will hook up a 4:1 and a 1:1 balun on the end of the ladder line and run a sweep with each balun.

4868. Matchbox Suggestions for Steve

Yahoo group: SkyWires
Date: 2015-06-20 10:51:03 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4810 Message: 4868

Sigi□s tip is good, but I would also add a 1:1 Choke between the tuner and
the antenna.
This can be a simple coax choke.

The reason is, we have two challenges here:
1) matching, and
2) common mode current on the feedline.
It is a good idea to place a choke between the feedline and the tuner, to keep the common mode current out of the tuner.

I have had good luck running high power with the choke that is pictured in the first and last picture in the gallery of pictures from my former QTH in Oklahoma:
http://www.dj0ip.de/my-station/oklahoma-2010/

For low power, use RG-58 instead of RG-213.
Use about 23' on about a 4" form.
The spacing with rope is optional but helps by reducing mutual capacitance between the turns.

Subject: AW: [SkyWires] Steve's Low Loop Resonance Test Results

Go an buy an autotuner (cg3000 or one of the sgc autotuners)

Put a choke (balun) on the input of the tuner (and also add chokes for the control and/or power cable) ... so the tuner is floating" (rf wise)

My friend andreas uses such a setup (ladderline fed doublet) with such a tuner and he can work all bands without touching any knob ... just qsy and transmit (and tuner does the rest

Your internal tuner can not do that (much smaller tuning range)

Using tuners in a row (the dentron and the internal tuner) is also not a good solutions (2 tuners = 2 times tuner loss)

Hello rick

I also use 2 "city trees" for my loop ... I did not ask ... I just used them

Sometimes it is easier to ask for forgiveness then ask for permission :-)

Everett... what comes out at lower end of the ladderline in your 160m loop highly depends on what ladderline length you use

I use different length for the different bands (added length is switched in with 2 banana plugs) ...

Rick

How do you add a choke on tuner output (if ladderline is used) ???

If the tuner is completely floating (rf wise) then there should be very low common mode current towards the rig ...

When that "input" choke has a high enough impedance then there is no way for cmc flowing towards rig/ground .... it is just blocked at the tuners input

Dg9bfc

That□s IMPOSSIBLE Sigi . . . you don□t even live in a city! (hi)

I tried that once when living in Kirchheim, near Munich.
I had one leg of a dipole crossing a street and tied to a tree.
It took about one week until I got a letter from the city telling me to
remove it or they would remove it and send me the bill.

Hello rick

I also use 2 "city trees" for my loop ... I did not ask ... I just used them

Sometimes it is easier to ask for forgiveness then ask for permission :-)

It is obvious that you did not look at my pictures, Sigi.

I said it is pictured in the first and last picture in the gallery showing
pictures of my QTH in Oklahoma.

It couldn□t be any simpler than what you see in the picture.
The coax is wrapped on a pvc pipe.
The bottom stub has a PL-259 attached.
The top end of the coax has 2 banana jacks soldered to it.
The openwire simply plugs in.

In this case I'm not so much worried about the common mode current towards
the rig as I am worried about the CMC getting into the digital electronics
inside of the tuner itself.

Without the choke on the antenna side, the CMC is free to play havoc with
everything inside the tuner.

Here's the link again:
http://www.dj0ip.de/my-station/oklahoma-2010/

Rick

How do you add a choke on tuner output (if ladderline is used) ???

If the tuner is completely floating (rf wise) then there should be very low
common mode current towards the rig ...

When that "input" choke has a high enough impedance then there is no way for
cmc flowing towards rig/ground .... it is just blocked at the tuners input

Sigi,

The ladder line is 450 ohm, 16 gage and 100' long. I would like to put a balun at the antenna, but we are going to pushed for time on field day. So I will have to work with the readings at the end of the ladder line.

You are right ... I live not in a city ... more rural (very small village)

I do not even have direct neighbours (no man mande noise except from my own house)

So ... what is correct term for that ?? village tree??

Maybe your problem was the crossing of the street?!?

I used a tree outside from my property ... but the loop is above my area (and NOT ACROSS THE STREET!!!)

Rick and Sigi,

My 1:1 choke is 2 stacked FT240-31 cores with 10 bifilar turns of 14 magnet wire inside of Teflon tubing.

Ok ... NOW I LOOKED AT THAT PICTURE

Did you measure the inductance of that ugly balun ???

What about the impedance jump from ladderline to the 50 ohms coax?? Would that not add another point for losses??

If on shack end you have something in lower ohms range (current spot) then your choke will work well ... but what if you have a high impedance spot at the shack end (a few hundred ohms or more) ... what does the mismatch between that choke and the ladderline do ???

Sigi . . . ☹
Ha ha! Stop thinking like an engineer for 30 seconds and just look at it again.
It seems engineers always search for the bad in things, and often miss the good.

We are on 1.8 to 30 MHz here, not 23cm.
THIS CHOKE/BALUN WORKS JUST FINE FOR THIS APPLICATION.

You know my approach to things: KEEP IT SIMPLE, STUPID! (hi)

This is not an idea or concept.
This is what I have used daily for 10 years, running about 750w of power into it.
In Oklahoma, I could work the entire world during big contests on 80m, usually with just one or two calls. 40m as well.

Africa, China, anywhere! As soon as it popped up on the spotting net, I worked it.
The antenna I was using in Oklahoma is shown in a couple of the other pictures. It was a simple short vertical dipole (openwire fed) with 9m long legs.

Previously in Germany I had used it to match a center-fed openwire-fed 80m dipole. I used it on all bands with an L-Network tuner.
AND
I also used it there with a short center-fed vertical (2x 6m), fed with openwire.
I used this on all bands from 80m thru 10m.
This short center-fed vertical was very good at working across the pond to stateside, as well as around the world, but it was not nearly as good on 80m as the larger one I had in Oklahoma. I could work the world with it on all bands, but sometimes I need 10 or more calls.

My contest scores don’t break any records, but are much higher than 60 or 70% of the other entries in the contests. In the big CQWW contests I generally turn about 1/2 million points in the SSB contest and 1 million points in the CW contest. You don't do that with antennas that don't work well.

We can search for non-plus excellence 'til the cows come home.
We can blow our bank account buying the unnecessary CR@P the engineers and marketing gurus would make us think we need.

But at the end of the day, there are lots of simple low cost solutions to nearly every problem that work 95% as good as the $5000 solution. Perhaps a wee bit exaggerated - - but not much!

Now to your questions:

"""Did you measure the inductance of that ugly balun ???"""

No; don't care what it is. It gets the job done.
Prior to using it, I burned up about half a dozen commercial baluns rated 2.5kW or more.
With them I had RF in the shack and got burned on the matchbox. Once I switched to using

this ugly balun, the problems ALL went away, but the performance remained.
THAT PRETTY MUCH SAYS IT ALL!

"""What about the impedance jump from ladderline to the 50 ohms coax?? Would
that not add another point for losses??"""

This is HF, not UHF.

If I feed a 450 Ohm openwire feedline to an 80m dipole on 40m, I have a 2500 Ohm antenna fed by a 450 Ohm (long) feedline. That is a jump of 5:1, yet we all know that the loss is so trivial that it can be neglected.

The jump for 450 to 50 Ohms is 9:1 but the coax is only 7m long.
Again the loss is trivial. Not saying there is none; there is loss, but negligible.

The gain is "a solution that works" and it only cost a fraction of what I spent on each of the commercial baluns I had previously burned up.

This solution works fine. Try it and you will see.

If you want it to work on 160m, add another 10' of coax to it.
Although, I used it on 160m as is, and had no problems.

I have several friends who use this including one who runs 1KW AM on 80m (in Tennessee).
I have never heard anyone come back and say they had any problems with it.

"""If on shack end you have something in lower ohms range (current spot) then
your choke will work well ... but what if you have a high impedance spot at
the shack end (a few hundred ohms or more) ... what does the mismatch
between that choke and the ladderline do ???"""

Well when I had an 80m dipole used on 40m, I did indeed have high impedance.
Yet I was able to match the antenna on all bands with my Ten-Tec Model 228B L-Network matchbox and run high power through it. I had no problems.

People with lots of time on their hands and nothing to do are welcome to try and calculate these losses, but I say, 'who cares.'
Regardless of what number they come up with, what ultimately matters is the S-Meter reading at the other end of the QSO, not some silly theoretically number that somebody calculated.

This one is so simple to build and so cheap, anyone can try it.

Mark,

Later I will post in the file section a spread sheet with venders and prices. Kitparts is not the cheapest place to go, but easy to order from. It is amazing the difference in prices from the different venders for the same core. You have to look at minimum quantiles and shipping cost with each of the venders.

Also, even if you ignore all the end effects, it still will simply
resonate high simply by the math!
Say your dead flat at 7.15 MHz, 3 X is 21.450, at the top of 15 too high.

>
> Usually 468/Freq gives the length you get the best match. So freq times length equals 468. Well, I've got so much going on with the low height, structure, etc. that the 468 constant isn't holding true. OK, well I have two of the three pieces to figure out the Casa Del KA0NEB constant don't I? Basically the new dipole is cut to 66' (I left some for trimming) and it's very happy at 21.2 mhz, so 66*21.1 gives us 1399.2 for the new constant. OK, if I want it to be happy around 7.2 then 1399.2 / 7.2 = 194.33 or 97.16 per leg? Of course I'm bending around the house so that may play in...anyway, on the right track here, all wet, or you need something to do anyway Steve, go play and report back?

Steve you solved part of the problem.
Well, the 20 meter problem is a bear. How about a radical approach.
If possible, Get 3 10 foot pieces of PVC water pipe that will telescope together.
Insert the smaller into the larger 6 to 10 inches and secure with self tapping screws.
At the feed point of the main antenna, add a 16.5 foot wire to each side of the feed point.
Run one vertically using the PVC to support it. Run the other horizontal along the roof eve.
You now have a good 20 meter DX vertical.

"It is a myth that antennas very low to the ground work better for NVIS
than when they are higher up."

I didn't say that it was. But there is evidence that it might be under
some circumstances. Claiming that it is myth does not make it so.

"The radiation angle is the same for these antennas when they are close
the ground as it is when they are ¼ wavelength in the air."

Pretty much so, yes. Although we rely on antenna modeling for that. Even
the modeling does show differences. The change in directivity amounts to
several dBs, maybe as much as 10 or more at lower angles.

"However the ground losses increase as we move it closer to the ground,
and as we get real close, the ground losses shoot way up."

Sure do.

"So a 80m dipole 15’ off of the ground is worse than one 40’ off of the
ground in all cases, NVIS, DX, anything."

Except that some find **by their own personal experience** that they are
better able to get successful contacts and more S/N with a lower antenna.
(I myself have not experienced this.)

Damn the theory, damn what the antenna books say (which is mostly theory
anyway); their hands-on experience tells them something, which may or may
not agree with what our imperfect antenna theory and antenna modeling says.

"However is you take the higher antenna and reduce your RF gain, or use
an attenuator, it will be quieter too."

Yes, there definitely is that. There even are NVIS opponents who argue
that NVIS is all horse-doodie anyway, because you can get the same effect
by switching in your attenuator.

And then there are those who find otherwise, that a low antenna behaves
differently than just switching in an attenuator with a higher antenna.

Is it because the theory and the modeling are wrong? Is it something that
the models show us but we don't interpret right? Is it something in their
particular environments that the models do not account for? Is it what
they were smoking? I don't know.

"Cebik did a paper on this once."

With all respect to Mr. Cebik, just about all his work is based on antenna
mathematical modeling, which is an imperfect "science." I respect just

about everything L.B. Cebik wrote and I go to (or used to go to) his works first when I had a question about a type of antenna. But I also realize there are limits to what the modeling shows us. NEC, even NEC-4, don't "do" grounds right. It's a collection of approximations, which, when taken correctly, work pretty well most of the time, if you avoid doing certain things. But it is not the rule by which the world (i.e., physics) works. I would trust Maxwell a lot more than I trust Cebik and Lewallen and Lawrence Livermore. But the problem is that you can't do very much practical with Maxwell's equations, the way you can with NEC.

IIRC, Fiedler's work was mainly based on practical experiments, not modeling, and he found even very low antennas had their place and were useful.

Regards,
Andy

From: Evan Rolek
Topic: 1641 Message: 4885

Like they say, all models are wrong/limited BUT some models are useful.

Models and such can be a starting point but site specifics can alter one's real world results.

The best antenna on paper doesn't yield as many contacts as a poor antenna that is actually installed.

Let's all enjoy our beloved hobby.

Guys,

Loadstone is a good place to buy ferrite, if you are buying several of the same thing. They don't list their prices, only the inventory on hand. You will need to send them a email to get cost and shipping charges.

I posted this as an XL spread sheet so that others can add to it and repost it with any added information.

4888. Andy and Rick's NVIS discussion

Yahoo group: SkyWires
Date: 2015-06-20 14:45:27 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4810 Message: 4888

(Changed the subject line; far too many topics already going on under that old subject line)

Andy,

We are beginning to approach full agreement.

We are fully in-sync on believing in practical experience and not placing too much faith in modeling.
Though modeling is generally my starting point before going to the field.

My opinion is, if the model does not support the practical experience, then the model is wrong.

But those on the other side of the fence claim, if the practical experience does not agree with the model, then we measured wrong.

So my reply is then:
THE RUBBER HITS THE ROAD ON THE AIR, NOT ON THE KEYBOARD.

The proof of the pudding . . . is A/B tests run over a longer period of time, not just once for ten minutes.

My question to those who claim their low dipole is better is, have they actually compared both?
Or are they just getting good results with a low antenna and stating an opinion.

So let me re-phrase my one statement and see if we can agree:

"It is a myth to claim that antennas low to the ground are always better NVIS antennas than those that are higher. In fact I would say that if the antenna is between 1/8 and 1/4 wavelength high, it is generally better than close to the ground antennas – though there are exceptions."

I can supply you with some backup examples, but not here. It’s what I did in the military 3 or 4 wars ago (hi). Back then we actually used hf for important stuff.

Most transceivers today are too sensitive.
This results in everything being louder, including the noise.

The modern cure is to switch in Noise Blankers and Digital Signal Processing Noise Reduction. Long before we had all of that, we just turned down the RF gain until we got rid of the noise and simply listened to a much weaker signal, but perfectly in the clear.

I still operate like that.
In fact the S-Meter in my radio always shows the signal strength of the wanted signal, even when I turn on a pre-amp, or throw in attenuation. It is rare that I ever use the NR or NB. It is also rare that my RF gain is above 50%.

Maxwell is my bible. I re-read his “Reflections” every now and again, lest I forget and start believing some of the marketing hype spewed out by the vendors!

Joe Ham has gone SWR crazy. And it's not his fault. The manufacturers have reduced the size of components in all the radios, then lowered the acceptable SWR rating of the radio. Then the vendors throw gasoline on the fire, telling Joe that he needs a $1000 antenna tuner to compensate for his bad antenna (with its 2.5:1 SWR). So Joe soon believes that 2.5:1 is a bad SWR, when indeed it can be a very outstanding SWR in some cases. As Maxwell said, to low of SWR can sometimes kill us!

I am unfamiliar with IIRC (Fiedler). It sounds like a "must read."
I will have to find that and read it.
A quick google found nothing.
Where can I find it?

> This means even an inverted V (abt. 50 Ohms) fed with openwire on its fundamental is going to present a load of 12.5 Ohms if you run with a 4:1 balun!

Rick, that is incorrect. The impedance seen at the transmitter end will depend on the length and impedance of the open wire, which acts as a transformer. A quarter wave section of 200 ohm open wire feeding a 50 ohm load will present a feed impedance of about 500 ohms. A quarter (or 3/4) wave section of 400 ohm open wire will present a feed impedance of around 1000 ohms and a 4:1 reduction balun would be more appropriate than a 1:1 balun.

It all depends on the length and impedance of the open wire, but it will be a transformer on quarter wave lengths and on most in between wavelengths. Only on a half wave length will it reflect the impedance of the antenna.

To use a city tree I think it was in how i asked. We have a code enforcement guy that goes around actually looking for stuff. He was out and about. I stopped him and got to chatting with what he was doing, when I found out who he was it occurred to me to ask, but I didn't ask if I could directly, we got to discussing the trees and how they fined someone for trimming one...he was fined because he went nuts and litterally left a tall stump. If they're in the power lines call them, if it's on your side away from the lines you can do it within reason. They allow Holiday lights to be placed in them which think about it, you got power running up a tree. I then asked if all that were OK, could I hide a wire antenna in them? He said sure, no big structures of course, but wire would be OK. If they damage it during tree trimming they are not responsible. Vadalism should be kept in mind. Getting the feedline out of the tree to the shack needs some thought since it's not really temporary like holiday lighting, but putting a pipe under the sidewalk or something is fine with them. Basically I didn't ask if I could install an antenna in a tree, I asked if I could run a wire in a tree and pointed out it was much safer than the other stuff they allow, he said fine, he'd even send a letter confirming our discussion, so I'm sure I'll be able to get a wire in them. Two maples, kinda messed up from storm and ant damage, but the city trims and hoses their trees with termidor a couple times a year so the trees are recovering and not being damaged further, should be there a while yet. About 35' tall, about 50' apart.

> dipped and the load peaked it was happy.

The Drake TR-4 was very limited compared to older equipment like the Johnson Viking II. The only "antenna" that it ever failed to load was a 3' fishing pole on 160m. 80m and up, it would load it! I had wire running between the wash line hooks in the basement and it loaded it fine on 2.2 MHz MARS frequencies! (Note I said it loaded the antenna, I didn't say how good the antenna was. But during special operations I would have 2 or 3 rigs on at the same time and antennas were a compromise.

Topic: 4810 Message: 4893

You are correct Ken. My mistake.
My 12.5 Ohms is what would be seen at the feedpoint if you inserted the 4:1 balun there.

And I agree with your transformation examples.

My point is, the 4:1 balun should not be used at the matchbox because its ability to impede common mode current is limited to a narrow impedance range. The 1:1 balun will work much better in this respect when SWR is high (at the matchbox).

The matchbox is there to do the matching and the balun is there it keep common mode current out of the equipment.

The worst case example is when the antenna system impedance at the matchbox is already low. With the 1:1 it remains whatever it is. With the 4:1 it is 4x lower, which is very bad.

With openwire, it is best to use a matchbox that has a very broad matching range and if it is not symmetrical by design, use a 1:1 balun between it and the feedline.

Rick, that is incorrect. The impedance seen at the transmitter end
will depend on the length and impedance of the open wire, which acts as
a transformer. A quarter wave section of 200 ohm open wire feeding a
50 ohm load will present a feed impedance of about 500 ohms. A quarter
(or 3/4) wave section of 400 ohm open wire will present a feed
impedance of around 1000 ohms and a 4:1 reduction balun would be more
appropriate than a 1:1 balun.

It all depends on the length and impedance of the open wire, but it will
be a transformer on quarter wave lengths and on most in between
wavelengths. Only on a half wave length will it reflect the impedance
of the antenna.

From: joel1847@...
Topic: 4810 Message: 4894

This is not entirely correct. Just by reducing the RF gain, you are only reducing the noise that you are *hearing* not the actual noise itself. If your noise level is 6 db and the signal being transmitted 3k miles away is only 3 db, you are still going to only hear that local noise. You won't hear that 3db signal at all and reducing the RF gain won't change that.

Joel
kj6dif
norcal

So a 80m dipole 15’ off of the ground is worse than one 40’ off of the ground in all cases, NVIS, DX, anything.
Although it might be quieter as far as noise goes.
However is you take the higher antenna and reduce your RF gain, or use an attenuator, it will be quieter too.
Cebik did a paper on this once. Perhaps I can find it. I’ll have to search my files.

That sure sounds encouraging.
However if it were me, I would only use the trees as corner supports.
I wouldn’t run openwire to them.
Thin wires are not really intrusive, but openwire is an eyesore to non-hams.
It's probably better to connect the feedline elsewhere.

Getting the feedline out of the tree to the shack needs some thought since it's not really temporary like holiday lighting, but putting a pipe under the sidewalk or something is fine with them. Basically I didn't ask if I could install an antenna in a tree, I asked if I could run a wire in a tree and pointed out it was much safer than the other stuff they allow, he said fine, he'd even send a letter confirming our discussion, so I'm sure I'll be able to get a wire in them. Two maples, kinda messed up from storm and ant damage, but the city trims and hoses their trees with termidor a couple times a year so the trees are recovering and not being damaged further, should be there a while yet. About 35' tall, about 50' apart.

I wish I could raise it higher Rick. Getting it above the orchard trees and it starts getting into the wind which requires a whole lot of supports for a wire that's over a quarter mile long. By keeping it below the canopy, I can run it safely through trees and use the trees as support points using electric fence insulators. Far from ideal, I know. But it's what I have up right now. Until I can figure something else out.

Well I will reply to my own dumb post below.
It can help once the antenna is high enough.
But increasing the height to at least 1/8 wavelength will do more than laying a ground screen under it.

Ken,

You boys up north must have had more money than we did down south.
My pocket book only sufficed for a Viking Ranger.
It could basically load anything, but I did use a J.V. Kilowatt matchbox when running my openwire-fed 80m dipole. That was 1963.

My RX was an old military HRO which I got through army MARS.
It had sliding coils, rather than plug in modules.
My dream RX was the Drake 2C but I never owned one.

The Drake TR-4 was very limited compared to older equipment like the
Johnson Viking II. The only "antenna" that it ever failed to load was a
3' fishing pole on 160m. 80m and up, it would load it! I had wire
running between the wash line hooks in the basement and it loaded it
fine on 2.2 MHz MARS frequencies! (Note I said it loaded the antenna, I
didn't say how good the antenna was. But during special operations I
would have 2 or 3 rigs on at the same time and antennas were a compromise.

Joel, that is not a very realistic example.
In your example, I would not hear him at all, regardless of what I did.

In real life, I might have a S5 noise level and a R4-S7 signal.
I reduce the RF gain to the point that the noise vanishes.
The desired signal is S2 without any noise, and is armchair copy; sounds like listening to FM.

This is how I operate daily.
However not every radio will work this way. Some do, some don’t.
I am running a Ten-Tec Eagle.

73 - Rick, DJ0IP

From: SkyWires@yahoogroups.com [mailto:SkyWires@yahoogroups.com]
Sent: Saturday, June 20, 2015 5:29 PM
To: SkyWires@yahoogroups.com
Subject: RE: [SkyWires] Steve's Low Loop Resonance Test Results

This is not entirely correct. Just by reducing the RF gain, you are only reducing the noise that you are *hearing* not the actual noise itself. If your noise level is 6 db and the signal being transmitted 3k miles away is only 3 db, you are still going to only hear that local noise. You won't hear that 3db signal at all and reducing the RF gain won't change that.

Joel
kj6dif
norcal

So a 80m dipole 15’ off of the ground is worse than one 40’ off of the ground in all cases, NVIS, DX, anything.
Although it might be quieter as far as noise goes.
However is you take the higher antenna and reduce your RF gain, or use an attenuator, it will be quieter too.

Cebik did a paper on this once. Perhaps I can find it. I’ll have to search my files.

Hi Joel,

I always wanted a Porsche; had to settle for a VW Beetle.
Hey, without dreams, what would life be? (!)

At the end of the day, we all have to make the most out of what we have, or as Forest Gump's mom said, "we just have to play the hand the good Lord gave us!"

I'm in a very restricted situation here too.
Found this QTH online while I was still in South Carolina.
My XYL was here already, house hunting.

I directed her to this place, she said "honey it's beautiful" and signed the lease.
It is beautiful for her flower garden.
But we are on a steep mountain side, with a yard sloping about 40 degrees.
No chance to put up a tower or beam.

Using googlemaps I was unable to see the mountain.

I learned two things in that process:
1. Never use googlemaps as the key decision maker
2. Never listen to your XYL…. at least not in matters as important as choosing a QTH.

Here's a shot of my place.
Here you can see why I only have a dipole and not a loop.
http://www.dj0ip.de/about-me/my-qth/
I could only run a wire east-west.

Rich,

I have never understood why people call these cloud burners.
They claim that most (/all) of the power goes straight up.
If we look at the model, there is power going almost everywhere, albeit the strongest direction is up. But there is power elsewhere too.

In 1979 I was on a 10 day DX-Pedition to Andorra.
My call sign was C31SE.
C31 was quite rare back then, especially on SSB. I worked CW and a couple other guys worked SSB.
My only antenna was an 84m (275') loop strung in the trees about 6 to 8m high - (max 26' high).
It was matched with a home-brew matchbox, link-coupled using alligator clips to change bands.

I made hundreds of 80m stateside contacts running just 50w.
Made a few thousand contacts altogether on 80 thru 10.
Only have one picture posted at the moment:
http://www.dj0ip.de/my-expeditions/andorra-1979/
If you look closely above the right side of the tent, you can see the home-brew openwire feedline.

In this case, it's not the model that's wrong but rather the people interpreting it.

From: Andy
Topic: 4810 Message: 4906

"It is a myth to claim that antennas low to the ground are always better NVIS antennas than those that are higher. In fact I would say that if the antenna is between 1/8 and 1/4 wavelength high, it is generally better than close to the ground antennas – though there are exceptions."

I think that hits the nail on the head.

About the 'proof' from people that their very low field-expedient NVIS antenna usually gives them better results than a higher antenna, I can't say. There's at least one guy on an NVIS forum who says he gets as good if not better results most of the time in NVIS situations with his low antenna, but I don't know the thoroughness of his comparisons. I only know they were based on years of observations with others in his general geographical area.

Maxwell ... sorry, this is my mistake for not being clear. We aren't talking about the same Maxwell! I was referring to James Clerk Maxwell, so-called father of the so-called Maxwell's Equations, which govern all electro-magnetics including light waves and radio. (And he came up with them decades before radio was discovered.) I always found it amusing that he and Walt W2DU shared the same last name, but it was coincidental. Many, including Einstein, considered James Clerk Maxwell to have been the greatest physicist in the world since Isaac Newton's time.

Fiedler is LTC David Fiedler, who researched NVIS and wrote (along with Maj Edward Farmer) a small book about it (now out of print) which was a collection of various papers he and others wrote. Much of the contents of the book can be found elsewhere, and the book itself was somewhat limiting.

From: siegfried jackstien
Topic: 4810 Message: 4907

Hmm just thinking a bit

Maybe that guy who had better results with a low antenna had lots of noise
or other stations that were coming in a low angle

And he wanted to speak "locally" (nvis) ....

Lowering the antenna would lower the overall signal (noise, other low angle
stations and the high angle stations also)

The net result could be that with a lower antenna the noise or unwanted
stations were lowered say 20 db while the high angle signals were maybe just
lowered 10db ... the end result would be 10 db plus in signal to noise

So "sometimes" or better say in some cases a lower antenna may help

4908. RE: [SkyWires] Slingshots DON'T work!

Yahoo group: SkyWires
Date: 2015-06-20 21:24:12 UTC
From: slr_65@...
Topic: 4752 Message: 4908

OK, it's confirmed...slingshots don't work, well for us anyway, it appears they do for some, but pneumatic canons DO work!

We put a fly casting reel on for the string, just duct taped it on, worked perfect though it did end up making a mouse nests a couple times, I think I'd opt for a covered reel.

Just three shots...50 psi which seemed about right last time with string, that landed on the roof...three houses down! Reduced pressure to 35 psi, hmmm, same darn spot! And the trail was good, but the light string drifted in the wind/high arc and drifted off the trees. We reduced down to 25 psi, aimed very close to the tree tops and a bit uncomfortably angled towards the power lines....and it tracked just effin' perfect! Hopped right where we wanted it, dropped right in the neighbors yard.

We used the light fishing string to haul up some paracord and then the paracord to pull up the wire. No issues pulling. I had to head home, have some stuff for my daughter's wedding preparations going on this evening, so I dunno if he got the wire hooked up yet or not.

I got home with my son and we had the launcher just sitting there...yeah, we popped one over the city trees! 25 psi and one shot, perfect arc right over the tops of them! I left them decorated with orange paracord until tomorrow! 8-) Seriously, these WORK! You DO need the reel though.

Fun stuff!

Ken,

Of course you are right. There is no question that having both is better than having just [either] one.
However if you only have one, it should be the 1:1.
Should you need a broader matching range than the matchbox can handle, then you can always insert a 4:1 in front of it.

The problem is, most people don't know how to recognize which one they need.
If you only have the 1:1, the biggest problem you can have is, it doesn't find a match on one band or another. But you see that.

If you only have a 4:1, you may think the balun is OK, while at the same time you also incur common mode current in the shack, causing all sorts of silly intermittent problems, and not understand why.
➢ Why does my SDR transceiver sometimes hang?
➢ Why does my fault lamp on the linear sometimes go on (intermittently)?
➢ Why does my power supply sometimes go into fault (pertains to older Ten-Tec power supplies)?
➢ Why is the speed in my keyer sometimes changing?
➢ Lots more, but I'll stop there.
All of this can be the result of common mode current getting into the shack as a result of using a 4:1 balun in front of the matchbox.
Easy cure: don't ever do it.

Most antennas can be matched by most matchboxes.
However when you take the decision to deploy openwire feedline and certain types of antennas, you need to understand that half of the matchboxes on the market can't cope with that, without using a 4:1 balun to help assist in the matching. BUT THAT IS WRONG.

The balun's main job is to block common mode current. If your matchbox can't cope with the impedance range to be matched, you may need to choose a different matchbox, but don't resort to a transformer balun, unless you also assist it by preceding it with a 1:1 balun.

This is not theory I read in a book.
This is experience speaking. I have the burned fingertips to prove it! (hi)

No, I don☐t agree.

I don☐t think there is that much difference in radiation angle between very
low and 1/8 wl high.
The antennas radiate (or receive) pretty much the same.
The biggest difference is in ground losses.

Here is perhaps the tricky part.
On 80m most of the time, signal strength is not important, at least not for NVIS.
Perhaps for long haul DX.

Just about anything you can put in the air that is close to full size and horizontal is going to receive and radiate fairly well.
What matters here is the signal to noise ratio, not the ultimate strength of the signal.
Low antennas reduce signal strength and noise.
The net change is zero.
So even with a low antenna, you still are able to work just as well as with a higher antenna.

I have to return to what I said earlier. Just reducing gain will often totally eliminate the noise, thus even though the signal to noise ratio never changed, if all you are now hearing is the signal, you get the impression it is much clearer.

Subject: AW: [SkyWires] Andy and Rick's NVIS discussion

Hmm just thinking a bit

Maybe that guy who had better results with a low antenna had lots of noise or other stations that were coming in a low angle

And he wanted to speak "locally" (nvis) ....

Lowering the antenna would lower the overall signal (noise, other low angle stations and the high angle stations also)

The net result could be that with a lower antenna the noise or unwanted stations were lowered say 20 db while the high angle signals were maybe just lowered 10db ... the end result would be 10 db plus in signal to noise

So "sometimes" or better say in some cases a lower antenna may help

Subject: RE: [SkyWires] Slingshots DON'T work!

OK, it's confirmed...slingshots don't work, well for us anyway, it appears they do for some, but pneumatic canons DO work!

We put a fly casting reel on for the string, just duct taped it on, worked perfect though it did end up making a mouse nests a couple times, I think I'd opt for a covered reel.

Just three shots...50 psi which seemed about right last time with string, that landed on the roof...three houses down! Reduced pressure to 35 psi, hmmm, same darn spot! And the trail was good, but the light string drifted in the wind/high arc and drifted off the trees. We reduced down to 25 psi, aimed very close to the tree tops and a bit uncomfortably angled towards the power lines....and it tracked just effin' perfect! Hopped right where we wanted it, dropped right in the neighbors yard.

We used the light fishing string to haul up some paracord and then the paracord to pull up the wire. No issues pulling. I had to head home, have some stuff for my daughter's wedding preparations going on this evening, so I dunno if he got the wire hooked up yet or not.

I got home with my son and we had the launcher just sitting there...yeah, we popped one over the city trees! 25 psi and one shot, perfect arc right over the tops of them! I left them decorated with orange paracord until tomorrow! 8-) Seriously, these WORK! You DO need the reel though.

Fun stuff!

Like they
say, all models are wrong/limited BUT some models are
useful.

Models and such can be a starting point but site
specifics can alter one's real world
results.

The best antenna on paper doesn't yield as many
contacts as a poor antenna that is actually
installed.

Let's all enjoy our beloved hobby.

Thanks for the suggestions, I just ordered the MFJ 993-B.

OK, it has a 4:1 current balun in it, but I sent the balun designs balun in to be converted to a 1:1 current balun, soooo, use it in front of this unit when using ladder line?

Sounds great.

You will find that this new tuner matches all bands, so now all you have to do is find a way to raise your loop another 20 ft! (hi)

I even splurged and ordered the interface cable for my radio!

I think the city trees are going to become end posts and we'll tie back to the house eaves for the other two, that will give a 35-40' to 12' slope and lengthen the loop, though part will still be too close to the house. If it works well enough I'll probably put up two posts on the ends of the house and raise, but for tomorrows playing the house will have to do.

You have heard, of course, "never say never", LOL. Actually the Elecraft K3 internal tuner is quite good (specs say it will match a 10:1 SWR) and it is better than many external tuners I have used. The external Elecraft tuner KAT500 has the same ranges.

While I do agree that most internal tuners are of limited range, I wanted to point out that the Elecraft is significantly better than most. My comparisons to the K3 internal are the Palstar AT2K, SGC-239, LDG RT-100. The K3 internal seems to do better than all of them.

ABSOLUTELY CORRECT.
All of the Elecraft tuners seem to be exceptions to the rule.
There is only one External Tuner that I know of that has a broader matching range than the K3's tuner, and that's the MFJ-993 (and its stripped down brother, the 991).

4924. Steve's City tree Loop

Yahoo group: SkyWires
Date: 2015-06-21 23:21:49 UTC
From: slr_65@...
Topic: 4924 Message: 4924

OK, as we pulled up one line slipped off the top of one tree and came down about half way. Really windy today, so no time to reshoot so we ran what we had.

I just ran a wire over the tall tree, half way down the and around the other tree and connected the ends to the low doublet on the front of the house. (hooks and bungies on the corners for straing relief, plus the wire is fairly loose in the trees).

5/9 to Phoenix, AZ! Dropped down and heard 9A7R from Croatia, threw my call out,,,5/9! 8-)

We'll get the rest of the wire over the other tree a bit higher...

Things are getting fun!

Steve, KA0NEB

IMHO this 'wide range' depends on your antenna system and the output
power you are using. I have the KX1 and KX3 with built-in a-symmetrical
ATU's. With 2 and 12 Watt output these matching units are doing very
well indeed.

When I use my FTdx5000 with Acom 2000A it's a different situation and
much harder, for all the antennas and matching units I bought/built/used
in the past decades ;-)

Hello Rick,

Yes, I do! Looking forward to see you again and meet all the others.

I will visit your booth at thursday afternoon. In the morning I will try
to find some interesting parts on the fleemarket... ;-)

73, Hans.

Hans,

That☐s great.
The Hamfest is not open on Thursday. It opens on Friday.
I will be there setting up the booth on Thursday, in case you do come on
Thursday.

73 - Rick, DJ0IP

IMHO this 'wide range' depends on your antenna system and the output power
you are using. I have the KX1 and KX3 with built-in a-symmetrical ATU's.
With 2 and 12 Watt output these matching units are doing very well indeed.

When I use my FTdx5000 with Acom 2000A it's a different situation and much harder, for all the antennas and matching units I bought/built/used in the past decades ;-)

You have heard, of course, "never say never", LOL. Actually the Elecraft K3 internal tuner is quite good (specs say it will match a 10:1 SWR) and it is better than many external tuners I have used. The external Elecraft tuner KAT500 has the same ranges.

While I do agree that most internal tuners are of limited range, I wanted to point out that the Elecraft is significantly better than most. My comparisons to the K3 internal are the Palstar AT2K, SGC-239, LDG RT-100. The K3 internal seems to do better than all of them.

4932. Re: Steve's City tree Loop

Yahoo group: SkyWires
Date: 2015-06-23 06:57:44 UTC
From: slr_65@...
Topic: 4924 Message: 4932

I'm not sure if I should change the subject or not...

Feedpoint...but it's kind of specific to my setup, so I'll leave the subject title alone I guess.

I have a 40 meter doublet under the front eaves, fed with 450 ladder line in the middle.

The loop is simply connected to the ends of the doublet, so the loop on the north side is a straight line. The loop then hooks to wire hooked to an insulator and bungie cord tied to a hook in the eaves. The wire goes up into the trees, across and back down to the other corner. Makes a D shape with the straight part on the north side.

Feeding on the high south side would be difficult to get pulled up as we're pulling from east to west. I could feed the east side pretty easily though I think. Or, just leave it where it's at as it's working.

It would be nice to move the feed to the eave right over the window to to the radio room though, and that'd allow for a very short feedline as the station is right inside the window.

Any particular reason to move the feedpoint, or it's working, leave it alone?

If you use 50 ohms ladderline for feeding ... then there is no need to make the feeding line very short (in fact you can make it a few hundred feet long and would not notice any difference) ... loss on the ladderline is VERY low

What I would do is I would model that antenna in mmana ... then see the lobes on the higher bands ... and move the feeding point (if needed) that the lobes point to the locations of greatest distance

OK, if I get the guesstimates could someone model it...I'm not up to figuring modeling out with my vision.

On the vision front...check up today, slight improvement in both eyes! They weren't expecting improvement in the right one, so that's good news. The good news is actually it's not moving backwards, moving forwards is truly a blessing!

The new loop is working well...logged Australia tonight!

I seem to have trouble with the carribean though, I can hear them fine, but don't seem to be able to make the trip. I can make Florida, but not as strong as other eastern states it seems.

I'm wondering if it's in a null of my antenna, but if it's in a null then the null affects receive also, correct?

So far about the only direction I haven't heard is north, but then again there's not much in the Dakotas and Canada.

I have heard Canada but I didn't catch where, north of me or west/east.

The mfj arrived and is working beautifully! It even matched my short loop to 160 neter, which is something my Dentron could never do!

Thanks for the suggestion, I'm quite happy!

I even ordered the rig cable, so I don't have to worry about reducing power or anything to tune, it does it automatically.

/Steve

Glad it worked out for you, Steve.

The problem with most people is, they are too lazy to do any research before buying and just like to gripe afterwards if the product does not do as they like.

Nearly every manufacturer publishes the specs of each of its antenna tuner products.
All the buyer has to do is know roughly the required matching range and then do a bit of research to find a box that can match it.

And the second problem is, when they ask things like "what matchbox do you recommend", they are asking for trouble.

Unless I specify what I want the matchbox for, there is not enough information to answer the question. The only correct answer to that question is, "what do you want to do with it?"

If someone answers anyway without asking more questions,and especially with "I've had good luck with XYZ", then that person has no clue what he's talking about and shouldn't be recommending stuff.

In your case you told us exactly what you wanted to do and it was easy to identify a matchbox that would do it.

Gud Luk!

From: slr_65@...
Topic: 4940 Message: 4940

I'm enjoying chasing both the WAS award and occasional DX.

I've been kind of random though and I'm thinking there is some science to this, one would need to a pick a time our fellow amateurs would be active, pick the right frequency, have the propagation, etc..

The propagation is probably the biggest variable. I was trying to read up on it and I ran across this software that looks kind of interesting. I hate to install software though unless I really have to, just seems to lead to grief when a system gets loaded up and with my vision I'm not up to reloads unless I gotta, then we'll see if I can pull it off.

DX Atlas: Amateur Radio software http://www.dxatlas.com/HamCap/

http://www.dxatlas.com/HamCap/

DX Atlas: Amateur Rad... http://www.dxatlas.com/HamCap/ High resolution World Map software for Amateur Radio. Geographic and Azimuthal proje...

View on www.dxatlas.com http://www.dxatlas.com/HamCap/
Preview by Yahoo

Has anyone used this software and would care to comment on it?

I"m surprised something like this isn't available on the net somewhere, but I haven't found any, though it just may be a matter of using the right search terms.

I would be interested in any and all suggestions and strategies.

DX isn't the only focus....looking at my WAS map I need figure a way to get the close states, and I seem to be north deficient, though I was hearing Canada this morning when checking out greybelt DX (not too successful this morning, though I did make Puerto Rico 57).

Fun stuff, a great distraction for me right now! When I was a kid Rhode Island and Hawaii kept me from my WAS...last night I worked Rhode Island...and he was a mobile to boot! (on 40 meters, that's a commitment in effort and equipment!)

Thanks, I'll take a look...I've been using the HHH net the last couple night and am enjoying it, it seems many need Nebraska so I'm kept a little busy.

I also found the Southern Cross DX Net this morning that seems pretty friendly. Aussies were on board but I couldn't hear 'em. Puerto Rico was also on though and I logged them easily.

Fun stuff, you have to appreciate those net controllers!

From: slr_65@...
Topic: 4946 Message: 4946

Hi Guys,

Everything I've done to this point is temporary, of course isn't everything temporary...unless it works! 8-)

To feed the antenna to the shack I'm coming throuh a window as I don't want to put hole through the vynel siding and through the sheetrock.

We have storm windows, there was an upper glass window that slid up a channel and it sat on a screen in the lower part of the channel, then there was a glass window that sat in a channel in front of the screen. Then of course there's the actual wood slider interior window.

For now I've removed the storm windows and screen and rigged a couple boards to support the ladder line coming in and through.

The xyl is rihtfully demanding that be cleaned up a bit...and it needs to be.

OK, upper window can go back in, in place of the screen I'm thinking a piece of plexiglass as it could be easily drilled, cut, etc.. The wires feeding through is a question though, just silicone the penetration, or use some of that uv stable pipe insulation used on a/c unit lines to cushion/seal the hole?

Once in I've seen where MFJ makes some window hookups, but they're kind of pricey. I'm thinking a simple wood frame with plexiglass screwed to it and then I could mount coax or ladder line hookups directly to it. I thought about masonite or something, if it were electrically insulative enough.

Once in the window the shack desk is immediately to the right of the window and is 6' long so any feeds in the shack can be kept short.

I have a balun being rewired to 1:1, should I bring the ladder line into the shack as I am now, or should I mount the balun to the back side of the window feed panel and hook it up there and bring coax on into the shack? If I bring the ladder line into the shack and have the balun in the shack then I could ground the loop during storms easily.

I'm thinking of putting a couple coax feed throughs in the window panel and a set of banana jacks for the ladder line plus a ground bar.

Nothing set in stone, just thinking out loud.

The ladder comes from under the eaves and just hangs down until it enters the window, I'm thinking a hook in the eave with some dacron to a stake and then loosely securing the ladder line to the dacron to keep it from flopping around.

Any thoughts, suggestions, etc. - I'd love to hear how you all route your wires and make it look xyl presentable. (part of my problem is the shack is in a room on the front of the house, I really gotta kick her out of her craft room and claim the back room for my radio

stuff...but she's bigger than me, and meaner...8-D).

Steve , your idea will work just fine. Let me give you a little information. Plexiglass will crack and split , no good for a pass thru. Use polycarbonate (trade name Lexan), you can saw it on a table saw, hand saw, file, drill & tap , shape it any way you want.
http://i1102.photobucket.com/albums/g453/KD0ZZ/PassThru.jpg
You can buy some at any big box store as shatter proof window replacement. Cut two strips for your pass thru, wider than you need, slip into the slot of you window and clear calk the over lap. Cut a little thin strip to take care of the gap where the open window over laps.
Left over parts can be made into a tote for your 2M rig and power supply.
http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00780.jpg
The little scraps make good center mounts for a dipole, look around in my album and you will see a lot of polycarbonate used even the rack for my HF rig.

Thank you Rich, I appreciate that!

The upper window has a channel on the bottom to set over the screen, so it should set on the polycarbonate without needing the joint siliconed. I'll work on it this weekend I think.

To bring the ladder line into the shack or not is the question though. I'm leaning towards doing that. I'm thinking I'll use banana jacks (good quality brass ones of course) at the window panel so I can quickly and easily unplug the ladder line from the current balun and ground it...we do get thunderstorms in Nebraska!

I'll post back as the project develops.

From: ab0re@...
Topic: 4951 Message: 4951

Greetings!

For Field Day this year our local group met at a ball park and were given permission to hang antennas from the light structures. We set up a large horizontal loop antenna using 4 light poles to give the loop a nearly-square layout. I measured the wire before it was hoisted up using a roller-wheel and we checked the resonance feeding it with coax at one of the corners. The resonant points were a bit too low, so we lowered/raised the antennas a few more times to get the dips in the ham bands. I suspect we ended up taking off about 25' more, so perhaps the roller wheel method of measuring was not too accurate.

I was pleased to see that, after tuning, the dips were where they were supposed to be and, being harmonically related as we go from 3550 to 7100, etc. Normally, at this point, I'd simply tap the "tune" button on my K3 to flatten out the elevated SWR. However, I noticed that towards the top of the bands (top of 75M, for instance), the SWR was quite high and I was concerned about feedline loss going through 100' of RG8. So, we swapped out the center insulator and fed it with 300 ohm window line through an MFJ-949E tuner (using a 4:1 balun inside the tuner).

The loop seemed to work okay, but tuning was a bit finicky at places, even with the wide range MFJ-949E tuner. I suspect that's because the 4:1 balun dropped the impedence too low (some places it was showing ~13ohms, whereas others around 1000+ ohms). After seeing how the VSWR was all over the place when fed with ladderline through a 4:1 balun, I'm thinking we may not have made the correct choice. The idea of a loop antenna to use on multiple bands as they're harmonically related kind of blew up in my face, as VSWR at the edges of the band was so high that I didn't feel comfortable using coax, and using ladderline through the balun was finicky to tune, so likely it'd be outside of the tuning range of many internal tuners.

My apologies for asking what's likely been asked many times before:

- Do people who use large horizontal loop antennas typically feed them with coax or ladderline?

- If using ladderline, is a 1:1 or 4:1 (or some other value) balun typically used?

- If one uses a 1/4 wavelength piece of 75ohm feedline at the feedpoint to convert the impedence, what effect does this have on higher-frequency bands (say if the loop were made for 80M with a 234/3.55 x VF matching section of 75ohm coax, what would the VSWR look like on 40M with us having two quarter waves there? It'd essentially be a half wave section of 75ohm coax on 40M which is "invisible" in the overall antenna system; right?)

Due to the issues we had I'm just trying to pick up on what we missed regarding using a horizontal loop on multiple bands. If the answer is to just use the loop on it's design frequency and not the harmonics, the large horizontal loop certainly wouldn't have been the right choice for us. We'd have been better off going with dipoles or OCFDs. That being said, it was quite fun hoisting the loop up to the 40' level and the birds loved a new place to perch, too. :-)

Thanks in advance for any guidance offered,

Dan / ab0re

I suspect you would have had better operation of the loop if you had bypassed the 4:1 balun and used a 1:1 balun, even a coax ugly balun with RG 213 would have worked.
Yes, others do use coax but not always successfully for multiband use. The best feed is open or ladder line or 300 ohm line. A 1:1 balun should be used at the output of the matchbox.
Using 75 ohm matching line then 50 ohm coax is good for single band use, not multiband.
I tried the SKYLOOP with the 4:1 balun at the antenna and coax to the matchbox.
Then switched to 300 ohm and 1:1 balun to matchbox and was surprised at the 1 to 2 "S" unit improvement.
Short coax runs, less than 50 feet, are not so bad but the losses are up to 10 times what the balanced line has.

Dan,

We also put up a Horizontal loop for field day, it was 574' long. We feed it with 100' of 450 ladder line. We used a MFJ antenna tunner and it worked on all bands without any tuning issues. On Sunday morning it was used on 10 meters the balance of the day and worked very well.

I had a large (700') loop fed with open wire. It was extremely difficult to load on 160 and 80. The K3 did a fair job, the Palstart AT2K was very touchy and took several minutes if I could get a match at all. I cut it down to 600' and then 500' (approx). Same results. 4:1 or 1:1 balun, very little difference. It worked okay if I could get it loaded but it wasn't any better than my other antennas. The remnants of that loop are now a 160m OCFD which loads much easier and works all the bands from 160 to 6 (I had a 900 mile QSO on 6m today using it.)

I believe the problem is not the antenna as much as it is the transformer effect of the open wire line. A quarter wave 450 ohm open wire feedline will transform low impedance to high impedance and vice versa. It's not just a piece of low loss feedline, it is an impedance transformer.

Ken WA8JXM

Of course that is true of the feedline on an OCFD too.

I feed my 40 m horizontal loop with 300 ohm transmitting twinlead for about 30 ft, then a 1:1 current balun, then about 50 ft of RG-213, to a Drake MN-2000 tuner, and works great as my primary monoband, 40 m antenna.

For all other bands I use an 80 m horizontal loop, fed with about 90 ft of 300 ohm transmitting twinlead, and then use a KW Matchbox, Palstar BT-1500A, as my monoband antenna (sometimes used on 40 m though).

Coax is fine for monoband configurations, transmitting 300 ohm twinlead, 450 ohm window line, or true open wire line, are perfect for multiband operation. When I use a balun, it is always a 1:1 current balun. I've never had an antenna where a 4:1 ratio would ever be better.

In a net on Sunday, some hams within 20 miles of me were using inverted Vs and dipoles, and had trouble hearing most of the stations in the net. Possibly due to propagation but the loop suppresses some of the noise and I heard all stations 5x9 (true value, not "contest" reports). Under adverse propagation conditions, I've found over the years that my loops have worked better than my vertical.

73,

Evan, K9SQG

I suspect we ended up taking off about 25' more, so perhaps the roller wheel method of measuring was not too accurate.

I was pleased to see that, after tuning, the dips were where they were supposed to be and, being harmonically related as we go from 3550 to 7100, etc. Normally, at this point, I'd simply tap the "tune" button on my K3 to flatten out the elevated SWR. How ever, I noticed that towards the top of the bands (top of 75M, for instance), the SWR was quite high and I was concerned about feedline loss going through 100' of RG8. So, we swapped out the center insulator and fed it with 300 ohm window line through an MFJ-949E tuner (using a 4:1 balun inside the tuner).

The loop seemed to work okay, but tuning was a bit finicky at places, even with the wide range MFJ-949E tuner. I suspect that's because the 4:1 balun dropped the impedence too low (some places it was showing ~13ohms, whereas others around 1000+ ohms). After seeing how the VSWR was all over the place when fed with ladderline through a 4:1 balun, I'm thinking we may not have made the correct choice. The idea of a loop antenna to use on multiple bands as they're harmonically related kind of blew up in my face, as VSWR at the edges of the band was so high that I didn't feel comfortable using coax, and using ladderl ine through the balun was finicky to tune, so likely it'd be outside of the tuning range of many internal tuners.

My apologies for asking what's likely been asked many times before:

- Do people who use large horizontal loop antennas typically feed them with coax or ladderline?

- If using ladderline, is a 1:1 or 4:1 (or some other value) balun typically used?

- If one uses a 1/4 wavelength piece of 75ohm feedline at the feedpoint to convert the impedence, what effect does this have on higher-frequency bands (say if the loop were made for 80M with a 234/3.55 x VF matching section of 75ohm coax, what would the VSWR look like on 40M with us having two quarter waves there? It'd essentially be a half wave section of 75ohm coax on 40M which is "invisible" in the overall antenna system; right?)

Due to the issues we had I'm just trying to pick up on what we missed regarding using a horizontal loop on multiple bands. If the answer is to just use the loop on it's design frequency and not the harmonics, the large horizontal loop certainly wouldn't have been the right choice for us. We'd have been better off going with dipoles or OCFDs. That being said, it was quite fun hoisting the loop up to the 40' level and the birds loved a new place to perch, too. :-)

Thanks in advance for any guidance offered,

Dan / ab0re

Steve, you can use any noncorrosive studs , SS, brass or what ever for a pass thru with a polycarbonate sheet. Some people will go off on the deep end .about SS having a higher resistance than silver but it is only the length thru window, no big deal.
I agree with the banana plugs and grounding but I moved mine inside and have them at the balun, I also use a 4:1 or 1:1 switchable balun.
http://i1102.photobucket.com/albums/g453/KD0ZZ/4to11to12.jpg
One time I disconnected the coax from the balun to the tuner but did NOT plug in the ground and woke up in the middle of the night with a static discharge going, pop, pop, pop from the balun to the top of the tuner case.
My loop can build up quite a charge.
You are on the right track with a ground.

Only if it is really a quarter wave. Random lengths (typical for "from the antenna to the shack") will have more or less random results.

Steve,

I used a piece of scrap 1x4 and then cut two pieces of aluminum sheet (home depot) to fit it. Screwed each sheet to the wood w/ about 8 or 10 small SS sheet metal screws on each side. I ran one (about 1/4") 3" piece of brass threaded rod thru both sides with nuts / washers and tied this to a ground rod on the outside with a few feet of some #6 (or is it #4?) solid copper wire (this ground rod is also tied to the service entry ground rod). On the inside my 'copper pipe' station ground connects to it.

I drilled holes and mounted seven 3" pass-thru SO-239s in it. That grounds the outside of those to earth ground which in turn grounds the shield of the coax at the pass thru. All the antenna coax comes to these and jumpers on the inside take them wherever they are currently plumbed up to. As antenna change over time it's easy to just re-jumper on the inside.

A small extra hole allows a rotor control cable thru. Mount balun on outside wall and a 3' jumper brings that to the pass-thru.

Mine is actually vertically oriented next to a window air unit in the garage but concept is same and provides needed grounding. This one has been in place for a couple of years now w/o issues.

Hi Skip,

Yeah, I gotta get to using the QSL bureaus and I LOVE that we can PayPal for envelopes and stuff with your group! It's also very nice we can download the roster. I participated in the 00:00 net last night. I'm not sure if I'll make the 04:00 tonight or not...I kinda stayed up too late last night and then couldn't get to sleep this morning (I'm taking high dose steroids and they're causing sleep issues). I did get a nap today, we'll see how I hold up as to whether I HF net at all tonight.

Thanks to all you guys that run the nets! It's much appreciated, maybe some day when I get up to speed on their operation, get a better signal out and little more accustomed and adapted to my new low vision I can figure a way to help out...I am the type who likes to get involved with the volunteer groups I join.

4964. Rapid disconnect for non-coax

Yahoo group: SkyWires
Date: 2015-07-01 03:33:58 UTC
From: Evan Rolek
Topic: 4951 Message: 4964

While I can and do disconnect my antenna connections in the shack, I also have rapid disconnects outside for my 300 ohm transmitting twinlead, and have used the same mechanism when I used 450 ohm window line. Basically I use banana plugs and jacks in weather-resistent boxes designed for 110 vac outlets. HOWEVER, one must be cautious with outdoor connections. The plugs and jacks that I use have nickel plating which resists corrosion. In addition, I use sparkplug boot release (a silicon based insulating grease designed for HV ignition systems) to coat the terminals. Not sure what the lifespan is but I have over 10 years on the originals and no problems running legal limit power. As a side note, I can get up from my easy chair, unplug the antennas, move the feedlines away from the house, and be back reading the newspaper all within 5 minutes. With onset of storms, disconnecting the antennas is quite easy.

Thanks for that Evan.
It is in line with my experience over the years.
I never had a loop permanently installed at home but have used it many times at field day and dxpeditions.
My conclusion was as your; the loop just seems to work better than other wire antennas at similar heights.
And it is usually quieter.

Subject: Re: [SkyWires] Field Day 565' loop - am I missing something?

I feed my 40 m horizontal loop with 300 ohm transmitting twinlead for about 30 ft, then a 1:1 current balun, then about 50 ft of RG-213, to a Drake MN-2000 tuner, and works great as my primary monoband, 40 m antenna.

For all other bands I use an 80 m horizontal loop, fed with about 90 ft of 300 ohm transmitting twinlead, and then use a KW Matchbox, Palstar BT-1500A, as my monoband antenna (sometimes used on 40 m though).

Coax is fine for monoband configurations, transmitting 300 ohm twinlead, 450 ohm window line, or true open wire line, are perfect for multiband operation. When I use a balun, it is always a 1:1 current balun. I've never had an antenna where a 4:1 ratio would ever be better.

In a net on Sunday, some hams within 20 miles of me were using inverted Vs and dipoles, and had trouble hearing most of the stations in the net. Possibly due to propagation but the loop suppresses some of the noise and I heard all stations 5x9 (true value, not "contest" reports). Under adverse propagation conditions, I've found over the years that my loops have worked better than my vertical.

Subject: [SkyWires] Field Day 565' loop - am I missing something?

Greetings!

For Field Day this year our local group met at a ball park and were given permission to hang antennas from the light structures. We set up a large horizontal loop antenna using 4 light poles to give the loop a nearly-square layout. I measured the wire before it was hoisted up using a roller-wheel and we checked the resonance feeding it with coax at one of the corners. The resonant points were a bit too low, so we lowered/raised the antennas a few more times to get the dips in the ham bands. I suspect we ended up taking off about 25' more, so perhaps the roller wheel method of measuring was not too accurate.

I was pleased to see that, after tuning, the dips were where they were supposed to be and, being harmonically related as we go from 3550 to 7100, etc. Normally, at this point, I'd simply tap the "tune" button on my K3 to flatten out the elevated SWR. How ever, I noticed that towards the top of the bands (top of 75M, for instance), the SWR was quite high and I was concerned about feedline loss going through 100' of RG8. So, we swapped out the center insulator and fed it with 300 ohm window line through an MFJ-949E tuner (using a 4:1 balun inside the tuner).

The loop seemed to work okay, but tuning was a bit finicky at places, even with the wide range MFJ-949E tuner. I suspect that's because the 4:1 balun dropped the impedence too low (some places it was showing ~13ohms, whereas others around 1000+ ohms). After seeing how the VSWR was all over the place when fed with ladderline through a 4:1 balun, I'm thinking we may not have made the correct choice. The idea of a loop antenna to use on multiple bands as they're harmonically related kind of blew up in my face, as VSWR at the edges of the band was so high that I didn't feel comfortable using coax, and using ladderl ine through the balun was finicky to tune, so likely it'd be outside of the tuning range of many internal tuners.

My apologies for asking what's likely been asked many times before:

- Do people who use large horizontal loop antennas typically feed them with coax or ladderline?

- If using ladderline, is a 1:1 or 4:1 (or some other value) balun typically used?

- If one uses a 1/4 wavelength piece of 75ohm feedline at the feedpoint to convert the impedence, what effect does this have on higher-frequency bands (say if the loop were made for 80M with a 234/3.55 x VF matching section of 75ohm coax, what would the VSWR look like on 40M with us having two quarter waves there? It'd essentially be a half wave section of 75ohm coax on 40M which is "invisible" in the overall antenna system; right?)

Due to the issues we had I'm just trying to pick up on what we missed regarding using a horizontal loop on multiple bands. If the answer is to just use the loop on it's design frequency and not the harmonics, the large horizontal loop certainly wouldn't have been the right choice for us. We'd have been better off going with dipoles or OCFDs. That being said, it was quite fun hoisting the loop up to the 40' level and the birds loved a new place to perch, too. :-)

Thanks in advance for any guidance offered,

Dan / ab0re

I tried the SKYLOOP with the 4:1 balun at the antenna and coax to the matchbox.

Then switched to 300 ohm and 1:1 balun to matchbox and was surprised at the 1 to 2 "S" unit improvement.

Dan, my loop is not square but a delta loop. It started out about the same length as you first try. Installed a 4:1 current balun at a corner , RG-8, then had to remove some to get a good SWR in the middle of the 40M band. The main use is 80 & 40. It preforms much better than my full size 40M vertical. I use the auto tuner on mt TS-590.

I support THIS answer.
Ken is right, the impedance can be all over the map.

The problem is, 450 Ohms is not always 450 Ohms and the velocity factor is rarely what we think it is. You should never assume the vendor gives you the correct number when you ask.

The best thing to do is the measure both with an analyzer.

From: ab0re@...
Topic: 4951 Message: 4969

Thanks everybody for the helpful info on the horizontal loop concerns I was having. Next time I'll try a 1:1 balun at the tuner vs a 4:1 and still feed the loop with ladderline, or perhaps ditch the loop all together to go with a different multiband antenna such as the OCFD.

As many have pointed out the impedence transformation feeding the loop with ladderline is likely what gave me headaches..... some bands it seemed like a 4:1 would be beneficial, whereas other bands (80M in particular) it would drop the impedence too low. Perhaps the ideal would be a switchable 1:1 / 4:1 balun. I noticed Elecraft offers one, but it doesn't look too hefty compared to the offerings from Balun Designs, etc (the core is pretty small). It would be nice to find a workable solution that'd be well within the range of my K3s built in auto tuner so I had one less piece of equipment to haul to field day.

73,

Yahoo group: SkyWires
Date: 2015-07-01 15:11:34 UTC
From: siegfried jackstien
Topic: 4951 Message: 4970

It is easy to homebrew a switchable 1:1/1:4 balun ...

What I did is I use 2 different length of ladderline (and no switchable balun) ... added length is switched in with just 2 banana plugs

The loop represents a low impedance on the 2 lower bands (for me 160 and 80) ... and with a quarterave line I transform that up in the range of 400 to 500 ohms ... and then back down with a 1:9 ... on higher bands the swr is always well below 1:3 (some exactly spot on 1:1!!) ...

So I have about 18m from loop to shack and add another 20m in between for 160 (and some of the higher bands)

On some bands the short run and on some bands the longer run is needed

Dan,

Building a switchable balun is a piece of cake… provided you can find a heavy duty switch, or hefty relays.
The wiring is dirt simple.

The most important part is, you MUST use dual cores, not a single core.
The single core is liable to cause common mode current issues.

Take a look at the second drawing on my web page:
http://www.dj0ip.de/balun-stuff/1-vs-2-core-baluns/

Here you see two toroids, each wrapped with a bifilar transmission line (may also be twisted pair).
Look carefully to the wiring on the input, vs. the output side.
The inputs are in parallel, the outputs are in series.

All you have to do is device a method to switch the output side from series to parallel and you have a 1:1 balun.

Now the icing on the cake.
If you also device a way to switch the input side from parallel to series, you will have a 3-way balun:
4:1 / 1:1 / 1:4

Why might we need a 1:4?

Well if space is tight, put up a 40m one wavelength loop.
For normal operations, the entire loop is a closed loop.
For 80m operations, if you open the corner opposite the feedpoint, it will work nicely on 80m.
Only problem is, the feedpoint impedance is just 12.5 Ohms (plus/minus depending on height, ground, etc.).
Here you can use the 1:4 balun to transform the 12.5 Ohms up to 50 Ohms.
Voila!

If I were doing this, I would use two FT-240=43 toroids for up to about 750 watts.
For more power you will need 4 toroids, stacking a pair together for each half of the balun.

Subject: Re: [SkyWires] Field Day 565' loop - am I missing something?

Thanks everybody for the helpful info on the horizontal loop concerns I was having. Next time I'll try a 1:1 balun at the tuner vs a 4:1 and still feed the loop with ladderline, or perhaps ditch the loop all together to go with a different multiband antenna such as the OCFD.

As many have pointed out the impedence transformation feeding the loop with ladderline is likely what gave me headaches..... some bands it seemed like a 4:1 would be beneficial, whereas other bands (80M in particular) it would drop the impedence too low. Perhaps the ideal would be a switchable 1:1 / 4:1 balun. I noticed Elecraft offers one, but it doesn't look too hefty compared to the offerings from Balun Designs, etc (the core is pretty small). It would be nice to find a workable solution that'd be well within the range of my K3s built in auto tuner so I had one less piece of equipment to haul to field day.

The horizontal loop is an excellent radiator which does not have to be resonant or a square to radiate but needs appropriate low loss driving point impedance matching to work efficiently. Also, maximizing the area inside of the loop will yield optimal results.

Evan's setup with a Palstar BT1500 true balanced antenna tuner and a 1:1 current balun on the input (between the xmtr and the tuning elements) instead of on the tuner output (between the tuning elements and the feedline) with open wire feedline is the optimal way to go.

Most tuners (T type) use 4:1 baluns at the tuner output which is not as efficient when incurring widely varying fundamental band to other band impedance on its output, such as a loop. (Part of the frustration I read in this post.) Most rigs use internal T type tuners too. Unlike the 4:1 balun on the output of a tuner, the 1:1 current balun placed between the rig and the tuning elements will always see its 50ohm designed load - in and out. A true balanced roller inductor tuner transforms the widely varying loads at the feedpoint to the 50 ohm current balun by moving the tuning capacitor across the output for Hi Z and switching it across the input for Lo Z matching. - See the Palstar BT1500 schematic for example at http://www.palstar.com/en/product-manuals/manual_bt1500a.pdf http://www.palstar.com/en/product-manuals/manual_bt1500a.pdf This setup is optimal for multiband operation but you can’t change bands on the fly with a push of a button.

Sorry Hank, but this statement is incorrect.

You wrote:

"Evan's setup with a Palstar BT1500 true balanced antenna tuner and a 1:1 current balun on the input (between the xmtr and the tuning elements) instead of on the tuner output (between the tuning elements and the feedline) with open wire feedline is the optimal way to go."

THIS IS VERY WRONG.

I understand many people believe this, but the real gurus of the industry explain why it is wrong.
You need only read W8JI's explanation or VK2OD's explanation.

Or as Tom Rauch, W8JI put it, "Ironically, moving the balun to the input only works when the balun is not needed!"

THE TUNER-BALUN MUST ALWAYS BE 1:1 CURRENT BALUN AND ON THE ANT SIDE - NO MATTER WHAT!

Also, it should NEVER be located inside of the antenna tuner. It needs to be external and in a non-conductive enclosure, such as plastic.

The two explanations why this is so are long but if you seriously believe the balun belongs on the TX side, you need to read these and either agree or come up with some darn good technical arguments why these two gurus are wrong.

VK2OD: http://owenduffy.net/blog/?p=4578
W8JI: http://www.w8ji.com/tuner_baluns.htm

The W8JI pages are very technical.
The VK2OD explanation is a bit easier to understand and he goes through and points out old myths about tuner baluns that have even been published in good antenna books.

Palstar finally got the message and in the newest BT-1500 has removed the balun from inside the enclosure and now offers a choice of two external baluns.

Slowly but surely the industry is progressing.

Again, replying to my own post:

It is not wrong to have a 1:1 current balun on the input side, but it must not be the only balun.

You MUST have a balun between the matchbox and antenna to keep common mode current out of the equipment.

Failure to do so can result in the tuner being very “hot” (RF-wise).

Hmmm ... you also can use an unbalanced tuner (balun on input)

I have seen several hams use that ...

A kelllermann balun on input of tuner

A hefty roller inductor and a hefty variable cap

That□s all

3 parts

A balun, a coil and a cap

That is correct and clearly described in Owen Duffy□s long document I recommended everyone read.

HOWEVER the fallacy is, most people believe they need a 4:1 balun. This is wrong.

Owen explains why.

So does Tom Rauch (W8JI).

4978. Palstar BT-1500A

Yahoo group: SkyWires
Date: 2015-07-02 18:52:41 UTC
From: Evan Rolek
Topic: 4951 Message: 4978

Information on the Palstar BT-1500A at the Palstar website and dealer information is consistent, that balanced line tuner still has the balun on the input, between the "tuner" and the transmitter, and that balun is inside the BT-1500A. There is no mention of an external balun for this tuner. However, external 1:1 and 4:1 baluns are mentioned in the information for some of the other Palstar tuners. Obviously something has changed and Palstar might have a balun external to that BT-1500A but I'm unable to find any documentation online; eventually it will appear I suspect.

73,

Evan, K9SQG

Again, replying to my own post:

It is not wrong to have a 1:1 current balun on the input side, but it must not be the only balun.

You MUST have a balun between the matchbox and antenna to keep common mode current out of the equipment.

Failure to do so can result in the tuner being very “hot” (RF-wise).

Subject: RE: [SkyWires] Field Day 565' loop - am I missing something?

Sorry Hank, but this statement is incorrect.

You wrote:

"Evan's setup with a Palstar BT1500 true balanced antenna tuner and a 1:1 current balun on the input (between the xmtr and the tuning elements) instead of on the tuner output (between the tuning elements and the feedline) with open wire feedline is the optimal way to go."

THIS IS VERY WRONG.

I understand many people believe this, but the real gurus of the industry explain why it is wrong.
You need only read W8JI's explanation or VK2OD's explanation.

Or as Tom Rauch, W8JI put it, "Ironically, moving the balun to the input only works when the balun is not needed!"

THE TUNER-BALUN MUST ALWAYS BE 1:1 CURRENT BALUN AND ON THE ANT SIDE - NO MATTER WHAT!

Also, it should NEVER be located inside of the antenna tuner. It needs to be external and in a non-conductive enclosure, such as plastic.

The two explanations why this is so are long but if you seriously believe the balun belongs on the TX side, you need to read these and either agree or come up with some darn good technical arguments why these two gurus are wrong.

VK2OD: http://owenduffy.net/blog/?p=4578
W8JI: http://www.w8ji.com/tuner_baluns.htm

The W8JI pages are very technical.
The VK2OD explanation is a bit easier to understand and he goes through and points out old myths about tuner baluns that have even been published in good antenna books.

Palstar finally got the message and in the newest BT-1500 has removed the balun from inside the enclosure and now offers a choice of two external baluns.

Slowly but surely the industry is progressing.

Subject: Re: [SkyWires] Field Day 565' loop - am I missing something?

The horizontal loop is an excellent radiator which does not have to be resonant or a square to radiate but needs appropriate low loss driving point impedance matching to work efficiently. Also, maximizing the area inside of the loop will yield optimal results.

Evan's setup with a Palstar BT1500 true balanced antenna tuner and a 1:1 current balun on the input (between the xmtr and the tuning elements) instead of on the tuner output (between the tuning elements and the feedline) with open wire feedline is the optimal way to go.

Most tuners (T type) use 4:1 baluns at the tuner output which is not as efficient when incurring widely varying fundamental band to other band impedance on its output, such as a loop. (Part of the frustration I read in this post.) Most rigs use internal T type tuners too. Unlike the 4:1 balun on the output of a tuner, the 1:1 current balun placed between the rig and the tuning elements will always see its 50ohm designed load - in and out. A true balanced roller inductor tuner transforms the widely varying loads at the feedpoint to the 50 ohm current balun by moving the tuning capacitor across the output for Hi Z and switching it across the input for Lo Z matching. - See the Palstar BT1500 schematic for example at http://www.palstar.com/en/product-manuals/manual_bt1500a.pdf This setup is

optimal for multiband operation but you can’t change bands on the fly with a push of a button.
What say?

The G 5 RV is a simple compromise antenna that is not particularly good.
People believing it is good, based on what they have worked have obviously never used a good antenna.

It has its place in ham radio back yards.
In some cases it requires less space to get on certain bands than other similar antennas.
But there is a price for this! (Performance)

The loop is totally different.
There is a price for the loop too: yard space.
But your are rewarded with performance

Well Hans, then you are also sometimes wrong because I am sometimes wrong.

I was just reading a WiMo catalog today and reading about Palstar matchboxes.

Yesterday I answered an email and I was WRONG.

I am going to write another mail now and correct that.

It was nice finally meeting you in Friedrichshafen last week.

4984. BT-1500 and Tuner Baluns

Yahoo group: SkyWires
Date: 2015-07-03 09:34:19 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4924 Message: 4984

In one of my replies yesterday concerning Tuner Baluns, someone mentioned the BT-1500 and that its balun is on the TX-side "where it belongs."

Normally when we speak of "Tuner Baluns", we are referring to baluns used together with an ASYmmetrical Tuner when feeding it with balanced openwire.

I said we must ALWAYS use a 1:1 Guanella Balun on the ANT side, not the TX side.
This applies to using with asymmetrical tuners.

The Palstar BT-1500 is a "Symmetrical Tuner", NOT an "Asymmetrical Tuner" which means it was designed to connect to a balanced line. As such, it does not require any balun at all on the ANT side. (I confused it with the AT-1500 which Palstar no longer makes.)

Placing a balun (in this case Guanella choke) on the TX side is always a good idea with any tuner, symmetrical or asymmetrical, and I do this with every tuner I have, albeit I use an external choke. In this case, Palstar already has on built in.

I like the BT1500 quite a bit and consider it to be one of the best truly balanced tuners on the market today. Unfortunately there are very few balanced tuners to choose from, and no link-coupled tuner that I know of.

I stand by my statement on which side of the tuner a balun belongs, but this refers to ASYMMETRICAL tuners, not symmetrical tuners.

You will find a very comprehensive list of symmetrical tuner, both past and present on my web site:

High Power:
www.dj0ip.de/antenna-matchboxes/symmetrical-matchboxes/high-power-atu-s/

Low Power:
www.dj0ip.de/antenna-matchboxes/symmetrical-matchboxes/low-power-atu-s/

Sorry for any confusion I may have caused.

4986. RE: [SkyWires] BT-1500 and Tuner Baluns

Yahoo group: SkyWires
Date: 2015-07-03 10:11:52 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4924 Message: 4986

Sigi, the least you could do is send me a private email when I say something silly like that and tell me I☐m fulla-bulla! (hi)

I think my head was on backwards yesterday.

Seriously though, I mixed it up with a normal T-Network that Palstar used to make which was also a 1500, but ☐AT☐, not ☐BT☐.

Palstar at least figured out that the balun NEVER belongs inside the matchbox.

It MUST always be external.

Owen explains why that is, very clearly in his blog (see link sent yesterday).

Palstar offer two external high power baluns for use with their asymmetrical tuners, a 1:1 and a 4:1.

I have heard (but I do not know if true or not) that the Palstar baluns are not very good and that one should rather choose a known good balun such as the Balun Designs Model 1113t ($60).

While in Friedrichshafen I wanted to find out and came armed with a screwdriver, but the dealer would not let me take apart the Palstar balun and look. BUYER BEWARE.

Whenever a dealer or OEM will not let me look inside, I have to assume he has something to hide.

Good balun OEMs such as Balun Designs shows you pictures inside of every product they build!

Believing that OEMs manufacturing baluns know what they are doing is like believing that every politician we elect is an honest man or woman. ☐We☐ have to know what we are doing and tell them what we want. If they can☐t deliver, find someone else who can.

Hmmm ... a good manufacturer would show its tuner either with an open case
... or with a plexi-glass case on a ham fair like Friedrichshafen

(I would do that ... just to show visitors how well it is built ... with how
big parts it is made ... build "like a tank" etc.)

... wrong tool ... you wanted to use a screw driver??

Makita lipo electric drill ... 18v ... switched to fast gear

And see the screws flying trough the complete room

Grin

... yepp sometimes even YOU are a bit hulla bulla ... hi hi

Information overload from friedrichshafen I guess :-)

Rick,
I'm the guy that you "flamed" when I choose to share my information with the group regarding my recommendation of the 1:1 balun on the balanced tuner input instead of the output. You said that it was "very wrong."

Well, I see that you corrected yourself and saved me from trying to figure a way to correct your misstatement. The balanced tuner setup is an excellent performer that I have used on my ~550ft loop.

My exploration of information regarding baluns coincides with Jerry Sevick W2FMI's (now unfortunately an SK) book on transmission line transformers and his other writings which I found interesting, and compelling wherein he used Ruthroff's mathematical loop equation derivations; expanded and applied it to balun design, and followed up with empirical results of various constructed balun/choke designs.

Fundamentally resonant long wire loop antennas generally exhibit a workable reactive component at harmonically related frequencies, and hovering typically between 30 and 200 ohms given a decent height above ground. This can be detrimental to balun efficiency while still being reachable to a "T" unbalanced tuner. That is why I prefer the balanced tuner setup with open wire line.

However, sacrificing a few db and using an internal rig T tuner with a balun is very convenient for push button on the fly tuning.

GM Hank,

I certainly apologize to you.

I was pre-heated by a recent article in QST which showed the balun at the wrong side of the tuner.

The misleading point here were words “tuner balun”.
I have never seen anyone speak of a tuner balun for a balanced matchbox.
Normally we are speaking of unbalanced or asymmetrical matchboxes when we speak of tuner baluns.

The balun must be at the point where the change between balanced and unbalanced occurs and with the BT-1500 it is after the matching has completed, on the TX side of the matchbox.

With most matchboxes used in this application, this point is where the transmission line meets the tuner. That’s why it’s called Tuner balun.

As recently as a month ago, Dean Straw had an article published in QST, placing the tuner balun on the TX side of the tuner. Now Dean is arguably one of the smartest men on the planed when it comes to antenna technology. Most of what I know about antennas and transmission lines, I learned from books that he wrote, but nobody knows it all. Apparently he has never worked much with openwire antennas and high power. He got that data point wrong and has mislead a lot of people with that article.

Besides the technical proof to the contrary, (W8JI, G3TXQ, VK2OD), I have the [RF] burnt fingers to prove he’s wrong.
If running an asymmetrical tuner and full legal power, try it both ways, and with all sorts of different openwire fed antennas.
You’ll soon see/feel where the balun belongs!

You have to be careful with Sevick.
No one has written a better book on baluns than his two books on TLTs and building and using baluns, but they are not flawless. He did a great job of showing us just how to build all kinds of baluns but a poor job of pointing out just when to use each of the different kinds. I don't think it was even the intention of the book to do so.
This not only leaves room for [mis]interpretation, it is in practice quite often misinterpreted, then quoted as proof of being right because Sevick said so.

A good example of how this can work against us is with the case of the 4:1 Guanella balun. Sevick show how to build a single core and a dual core version of the 4:1 Guanella, yet never implies that there might be any difference in their usage, when indeed there is significant difference.

The single core works like a champ in networks with floating transmission lines, but can break down entirely in antenna applications. At that point it doesn't fulfill the job of a balun.

This is because hf antenna all have a relationship to ground and are definitely not floating. When ground is introduced to the single core, it not only fails to impede common mode current, it actually generates CMC!

Yet for many years, in fact to this day, most balun manufacturers have no clue about this and every company I know of selling OCFD antennas uses the single core version, which is the major cause of malfunction of OCFD antennas. IMO, that is why the OCFD antenna has such a flaky reputation - misinterpretation of Sevick and then failure to deploy the correct type of balun.

I personally have always been a fan of the link-coupled tuner, such as the Johnson Viking Matchbox or the improved version of it built by Annecke in the 1980s and 90s. We had far less trouble with common mode current using these than we did with any other tuner design.

Since I always had two openwire fed antennas and only one high power (Annecke) symmetrical tuner, the second antenna had to use a tuner and balun. I tried all kinds* of commercial and home brew tuners and all kinds of baluns (the ones recommended by the “exerts”, called “Remote Balun”). I burned up a slew of baluns as well as burnt my fingers and lips all the time.
(*never tried a balanced T or balanced L tuner; I don't know if they even existed back then).

Finally about 15 years ago, K4TAX instructed me to only use a 1:1 current balun on the ANT side of the tuner, and when I did, all of those problems magically went away.

The skyloop only varies between 30 to 200 Ohms, though feedline length can transform that. The situation gets worse when feeding a resonant dipole on an even harmonic frequency. Here the impedance can be thousands of ohms at the feedpoint and all over the map at the TX end of the feedline.

From: Andy
Topic: 4924 Message: 4990

Rick,

I still don't follow you, and have a rather hard time believing some things you write, although I would like to. So many things you write contradict what you previously wrote, or appear to do so. (I am setting aside most of the mistake about the BT1500/AT1500.)

But addressing this one, that still seems wrong:

"Palstar at least figured out that the balun NEVER belongs inside the matchbox.
It MUST always be external."

And yet, the balun is internal in Palstar's BT1500A balanced antenna tuner, the same one that I believe you said they got it right (i.e., NOT the AT-1500).

Why does Palstar still not get it right, even after they figured it out?

More importantly, why MUST it be external?

The only two reasons I can see for having it external, are (1) airflow, if the balun gets really hot (in which case you probably have worse problems to worry about), and (2) to make it easier for the owner to replace the manufacturer's balun with one that is better. Other than that, I can think of no reason why the balun "MUST" be external.

In fact, isn't it better being internal? The connection from it to the TX side of the matchbox, is probably coax, because most matchboxes have an SO-239 as the signal input port -- although I'm willing to accept that a matchbox/ATU might exist that has binding post inputs on the TX/amp side. So with the balun external to the matchbox, and given the fact that the SO-239 probably does not "float", and connects to the chassis, that would make the entire matchbox case "hot". Not a good idea!

Whereas if the balun is internal to the matchbox case, the case stays at ~ground potential and all the balanced circuitry is inside, cleanly isolated from the case.

Yes? No?

Owen Duffy seems to prefer an external balun to get better airflow, and to reduce stray common-mode capacitance. I find it hard to believe that the latter is not easy to avoid.

Is there a commercial matchbox out there that comes in two or more shielded enclosures?

Regards,
Andy

GM Andy,

When talking about matchboxes, we have to understand that there are two classes of matchboxes, symmetrical and asymmetrical.

It is also important to understand that there are about 30 or 40 matchboxes (or antenna tuner, if you prefer) on the market but only about 4 of them are symmetrical matchboxes and these represent only about 1% of the market. ALL others are asymmetrical.

As such, when we speak about matchboxes at all, we are nearly always speaking about asymmetrical matchboxes.

Asymmetrical matchboxes require a balun to keep common mode current out of and off of the matchbox.
This is generally known as the "Tuner Balun."

So when I see the words Tuner Balun, I associate them with the balun on the output side of the tuner, between the antenna and the tuner.

>>> More below, directly below your text.

Subject: Re: [SkyWires] BT-1500 and Tuner Baluns

Rick,

I still don't follow you, and have a rather hard time believing some things you write, although I would like to. So many things you write contradict what you previously wrote, or appear to do so. (I am setting aside most of the mistake about the BT1500/AT1500.)

>>> No problem, I did not understand baluns for the first 48 years of my ham career. I thought I did but kept learning what I had previously understood was either partially or totally wrong. My learning resources (in alphabetical order) were G3TXQ, GM3SEK, K9YC, VK2OD, W7EL, W8JI, and of course Sevick, W2FMI.

But addressing this one, that still seems wrong:

"Palstar at least figured out that the balun NEVER belongs inside the matchbox.
It MUST always be external."

And yet, the balun is internal in Palstar's BT1500A balanced antenna tuner, the same one that I believe you said they got it right (i.e., NOT the AT-1500).

>>> Let's leave this BT-1500 out of the story for now and stick with tuner baluns. If you like we can talk about this one separately. Totally different situation. Of course its balun is in the right place with this type of matchbox, but it is not the typical "tuner balun." When I said Palstar got it right, I meant that for their asymmetrical matchboxes (i.e. AT-2K), where they dumped the internal 4:1 balun and offered an external 1:1 choke balun.

Why does Palstar still not get it right, even after they figured it out?

>>> I don't believe I said it quite like that. I said Palstar got it right with respect to moving the balun outside and dumping the 4:1 internal balun. That part is certainly right.

>>> There's more to the story:

>>>1. They offer a choice of external balun, either 1:1 or 4:1. Now the 4:1 might occasionally be batter for matching very high impedances, but in that case it is worthless for rejecting common mode current, thus is no balun at all. You must always have a 1:1 current balun as the tuner balun and if you tuner cannot match the required range, either adjust the length of feedline or insert a 1:4 transformer (which by the way can be a 4:1 balun). The naming is very tricking here. With the transformer, we want to step up from 50 to 200 Ohms (1 to 4), but when we use a balun to do that, we use a 4:1. Balun naming typically splits the word in two: BAL - UN, and we state the number for the BAL side first, then we state the number for the UN side second. Confusing indeed! Apparently Palstar still doesn't understand what happens to a 4:1 balun when it does not see a perfect match. Much different than when a 1:1 balun does not see a perfect match!

>>>2. BASED ON HEAR-SAY information, not known facts to me, I have heard that the new external Palstar balun is not good. I have heard of it burning up, the user looked inside and found it was inferior. Can't remember the details, but my first take was, "OK to buy the Palstar, but buy the balun elsewhere, or wrap your own."

More importantly, why MUST it be external?

The only two reasons I can see for having it external, are (1) airflow, if the balun gets really hot (in which case you probably have worse problems to worry about), and (2) to make it easier for the owner to replace the manufacturer's balun with one that is better. Other than that, I can think of no reason why the balun "MUST" be external.

>>>Well those are already two good reasons. When it's getting really hot, you are not using enough cores. Perhaps you need 2, 3, or even 4 cores. These generally won't fit inside. If it does get hot and burn up, I prefer it to do that outside of the matchbox, not inside.

In fact, isn't it better being internal? The connection from it to the TX side of the matchbox, is probably coax, because most matchboxes have an SO-239 as the signal input port --

>>> Yes, it is coax but I don't see that it makes any difference. The line between the matching network (coil and capacitors) is should be Teflon coax to either the balun, or the SO-239. Maybe I didn't understand your point.

although I'm willing to accept that a matchbox/ATU might exist that has binding post inputs on the TX/amp side.

>>>Why this? All TX today have coaxial outputs. Besides, the balun is on the ANT side of the matchbox, not the TX side (remember, we are leaving the BT-1500 out of this).

So with the balun external to the matchbox, and given the fact that the SO-239 probably does not "float", and connects to the chassis, that would make the entire matchbox case "hot". Not a good idea!

>>> No hotter than when feeding coax to it. Remember, RF current flows in two directions and when we have coax instead of openwire, it flows directly through the SO-239 and onto the chassis. But this is differential current (good current). It is the common mode current that is dangerous and if we don't choke it before it reaches the matchbox, it will do nasty things in our shack.

>>> Andy, the primary job of the balun is to remove common mode current from the scenario by impeding it. A really good choke balun in between the matchbox and the antenna will remove common mode current. The problem is, you can't buy really good choke baluns. The stuff the OEMs are selling us don't use ferrite with high enough permeability. Duffy points this out. Of course they work OK a lot of times, but whenever we are confronted with a bad case of common mode current, they are insufficient.

>>>With coax, there is absolutely no difference. The RF current between the TX and Antenna needs two wires. It is alternating and always flowing to and from the antenna. The amount of current is (supposed to be) exactly the same in both wires, regardless of whether they are parallel or in the form of a coax. They are also 180 degrees out of phase at any one point along the transmission line.

>>> Please keep in mind that although openwire feedline has just 2 wires, coax feedline has 3 wires: 1) center conductor; 2) inside surface of the shield; 3) outer surface of the shield.

>>> Differential RF current (the good stuff) flows on 1 and 2. Common mode current flows on 3. 1 and 2 are supposed to be equal all the time, but eventually 2 meets 3 (at the SO-239) and unbalances the scenario - unless we choke the common mode current sufficiently before it reaches the chassis.

>>> Common mode current is an additional current flowing on just one of the two wires, thus unbalancing the normal current flow. W7EL does a good tutorial of this in his paper on what baluns do and how they do it. The balun's most important job is to block this, thus keeping the flow of current in the transmission line equal.

Whereas if the balun is internal to the matchbox case, the case stays at ~ground potential and all the balanced circuitry is inside, cleanly isolated from the case.

Yes? No?

>>> NO! (hi); The circuitry inside is UN-balanced, not balanced. Half of it goes to ground. Only the 4 symmetrical matchboxes are balanced inside. Once the current flows through the balun (regardless of whether it is internal or external), it enters the matchbox where one side is grounded, so it flows on the chassis. But this is the differential current (the good current), not the common current - assuming your balun is doing its job. So that's alright.

Owen Duffy seems to prefer an external balun to get better airflow, and to reduce stray common-mode capacitance. I find it hard to believe that the latter is not easy to avoid.

>>> I fully agree with the latter. We need to avoid stray capacitance. Every commercial matchbox with an internal balun has always had the balun strapped to the chassis, with just a tiny piece of insulating material. This is not good. If the matchbox case were plastic and you had lots of air inside, then you could probably mount it inside and be good.

>>>One of the simplest and effective baluns to build is simply coax wrapped onto PVC. Most people simply wrap it scramble-wound (less good), or close-wound onto PVC (better). However I take it one step farther and wrap a nylon rope between the individual turns of the coax to help reduce mutual capacitance.
See: http://www.dj0ip.de/my-station/oklahoma-2010/

Is there a commercial matchbox out there that comes in two or more shielded enclosures?

>>> Not that I know of and I don't understand why you would want that.

>>> Final thoughts on this: The sole purpose of the balun is to keep common mode current (CMC) OUT of the shack and equipment. CMC is a funny, unpredictable beast and just how much you might have depends on many things, including the power level that you are running. It is ludicrous to believe that one single balun that fits inside of the matchbox will always be capable of fighting of CMC, no matter what. Sometimes we get by with practically nothing (i.e. operating QRP) but sometimes we need a ton of CMI (common mode impedance). In which case we will need to beef up the balun considerably.

>>Placing the balun outside gives us the flexibility to scale the balun's choking ability when required.

>>> "Balun" is a very complex subject and the biggest problem with them exists between the ears of the operator. They seem to believe a balun is a balun is a balun and as long as they have anything called "balun" they are alright. NOT!

Regards,
Andy

4992. TUNER BALUNS

Yahoo group: SkyWires
Date: 2015-07-06 16:46:54 UTC
From: Rick - DJ0IP / NJ0IP
Topic: 4924 Message: 4992

Few subjects have been so terribly misunderstood in our hobby as tuner balun.
It’s bad enough that the poor hams don’t understand it.

Worse yet, apparently none of the antenna tuner manufacturers fully understand it, but at least they are starting to come close. Both Palstar and MFJ (including Ameritron) have changed their tuner balun strategy at least once in the past 5 or 6 years. Neither are without flaws in their approach.

Just as bad are the balun manufacturers. Most of them have no clue about which baluns fit which applications. They simply build them all, offer them all for sale and leave the choice up to the ham. If they recommend something at all, quite often it is wrong. One exception here is Balun Designs. Bob is quite knowledgeable.

Today I have written a paper on this topic in layman terms, using as little technology as possible in the explanation. I hope it is clear to most readers.

At the bottom of the page I list several links to professional sites where the technical justification for what I have written is explained in very technical terms.

The final link is to one of my own pages, where I simply have a list of links to even more related and supporting documents.

I clearly do NOT consider myself a technical guru.
I’m more of a technical blogger, relying on others to supply the meat.
I try to remove the math and explain to others the benefit in using the correct solutions rather than the popular solution.

Here's the link to the page:
http://www.dj0ip.de/balun-stuff/tuner-baluns/

Hi Guys,

My son is getting interested in the radio, but I like to use headphones so I'd like to split the headphone output so we could use a pair.

My Kenwood is mono audio but it puts it out on both channels, so it's compatible with mono or stereo headphones.

I'm thinking one of those headphone splitters that has an input and then four outputs, each with it's own volume control, would be the move. Something like this:

Pyle-Pro PHA40 4-Channel Stereo Headphone Amplifier, Free Shipping, New http://www.ebay.com/itm/Pyle-Pro-PHA40-4-Channel-Stereo-Headphone-Amplifier-Free-Shipping-New-/141414508408?pt=LH_DefaultDomain_0&hash=item20ecf62778

"Am I on the right path here?"

That probably works fine.

The simplest method, is just a "Y" splitter cable with one plug and two jacks. The rig's headphone output probably doesn't mind driving the parallel impedance of both headphones (there could be exceptions, but extremely rare). But if one person wants it louder and the other quieter, then you have a problem. Also, if one headphone is mono and the other stereo, the mono one probably shorts out the right channel of the stereo headphones.

The amplified headphone DA would be the most versatile, but costs more, and needs power.

From: w6mob@...
Topic: 4998 Message: 4998

All

I had good success with modeling and building a 283 feet loop at about 40 feet high.
I remember that for smaller loop, at least, increasing the area and/or the number of turns of wire will improve the voltage across the terminals.
So my question is has anyone tried to use multiple turns or wire? If so what type of results did you see?
I wanted to ask before I go and try to put up 4 or 8 turns of 283 feet all ziptied together.

Cheers
Mick

Paul,

I like and use Flexweave, 14 gage, with the Poly covering. I am using 275', supported in 4 corners. It is running in and around trees. You can order the wire from Wireman, https://www.thewireman.com/antennap.html it is his item 542.

I don't know how you plan on feeding it, if you are going to use coax, then you might want to look in the files section of the SkyWires at a article that I posted "Loop Balun Experiment". It has a lot of information that might be of value to you.

I have a 550ft horizontal delta loop and have often wondered the same, if a extra run would help.
What would your spacing be?? Would you run the wires in a parallel setup or series?? Please keep us informed.

Unlike most, I don't have a "one size fits all" choice for antenna wire. When selecting antenna wire the considerations for me are power handling, conductivity, resistance to airborne contaminants, mechanical strength, and visual cross section. Ease of use and cost are in there but only as tie breakers. I really enjoyed using the "copper rope" or woven copper strands that are available from a number of vendors; I used the insulated style. Easy to use, easy to solder, etc. etc. but does have limits when subject to falling tree limbs, hi hi. For my current applications (horizontal loops in trees) I use #13 stranded copperweld, insulated, with a tough black jacket. The black color aids in disguise among the trees, it is strong, and works well. But, my selection is optimum for my particular installation and in no way is it one size fits all. Durability with regard to falling tree limbs is a big issue with me and the current antennas have held up well for 10 years. In this day and age, there are probably few QTHs where bare wire is acceptable due to moisture and contaminants.

Good luck with your selection and installation!

Hi Jean Claude

Yes, we’re not accustomed to this much heat.

I canceled several outdoor activities during the past couple of weeks.

I used to use US Army twisted pair, but I like the WIREMAN stuff much better. Don’t have to full with untwisting it.

The price is steep “by the foot” but I usually buy in 5 or 10 MILE increments. It’s a bit cheaper that way! (hi)

Rich,

I was asuming I would bundle them tightly with zip ties and run them in series. So if I ran 4 loops I would have a total of 1,132 feet around an approx 80x60 rectangle.
I am going to try to model it in Eznec before I try to build. Plus asking the group for advice.

Cheers
Mick

The far leg of my delta lop is thru some trees.
http://i1102.photobucket.com/albums/g453/KD0ZZ/160%20Loop/trees010_zpse5180867.jpg
I was not able to get my wire to the top because of multiple interference.
I made a antenna launcher from PVC and now can go over the top. I am now
wonder if I should add a higher wire and what effect would two wires
have. My spacing would vary so there would be a small difference in length..
Slightly wider bandwidth??

I don’t think that is a good idea. There will be too much mutual coupling. It would be better to space them, but I have no idea how much spacing is required.

Ken,

The life of the antenna wire depends on the contaminants in the air in the respective QTH. Too, depending on the contaminants, there might be an interaction with amount of rain and other forms of moisture. At my QTH, there is always abrasion due to tree limbs coming down (sometimes not seen for weeks and hanging limbs cause abrasion via movement due to wind), squirrels trying out the conductors, etc. In addition, areas near the ocean salt spray are particularly vulnerable to the effects of the atmosphere on bare copper and aluminum. With uninsulated copperweld, abrasion of the outer layer of copper (which varies in thickness by brand) exposes the steel core which then rusts and ultimately vulnerable to failure. Again, for me, I've had excellent experience with insulated, stranded copperweld, #13, but it may or may not be suitable for others and their respective goals and constraints. I am more than pleased with the lifespan of my current antenna wire.

73,

Evan, K9SQG

Hi Paul,
Do you mean a Loop or a Long Wire Antenna? You will get a lot of contradictory feedback on this subject, but, here are my thoughts...

If you think that there is a chance for branches and leaves to contact the wire you might want to consider insulated stranded copper wire which very marginally affects the electrical length and 12awg wire can be purchased at Home Depot type stores or electrical supply.

Personally I don’t like copperweld as it is difficult to work with and if it is cheap it will rust through and disappear. The fine multi-strand flexweave with insulation did not work well for me with 2 problems. If the insulation gets cut or chafed (say at the insulator tie points) you will get moisture trapped inside the wire and make it weak and difficult to fix. Splicing it is very difficult to do once oxidized inside the fine strands of the wire. However the 12awg flexweave's supple property is great for making insulated open wire feed line with spreaders un-compromised by icing problems (unlike the typically sold ladder line) as long as it is not stressed, cut, or chafed.

I had good results with 12Awg 7 strand all copper wire that I purchased from therfc.com in PA purchased by the foot (owner is Joel - will help with recommendation) which was strong enough to hold up as a 550ft loop around my yard for 12 years now and light enough to be workable and pulled with minimal catenary droop. It will last a long time, doesn’t fatigue or stretch, and if it does need repair it is easily fixed with spiral tying and solder. I found that out after Superstorm Sandy dropped trees on my antenna wire. Additionally it is strong enough to withstand icing up in the winter if that is of concern and support lines should be strong and not too big of a diameter to prevent large icing buildup on them with the resulting sag - and it’s fun to watch the birds try to stay balanced on the line as it sways.... Putting up a large loop is fun, and good exercise after walking a few miles to adjust the tie points.

That’s my 2 copper cents....

OK the SARK 100 Mini 60 arrived and I've played with it just a little bit.

The display is kind of small for me to read, but magnifying glass brings it up nicely.

I layed with my manual tuner and got the SWR to 1.0 to 1, but put the SARK on and it says my SWR is aroound 5 to 1? And, adjusting the tuner doesn't seem to make much difference to it.

Do these need calibrated, or does it need to put more out or something?

I found a manual for them...it appears this may be due to low battery power. I assumed because it powered on it was good to go, but I plugged it into the usb port and the light lit up red and it's been charging for a bit now, we'll see how it behaves when it's fully charged.

Now to figure out the software for it...fun with low vision...

The SARK has instructions for building 3 dummy loads.

The dummy loads are used to calibrate the device.

Dummy loads are made of resistors.

In each case, I used 2 tiny 1/4w resistors to get within 1% of the required value.

I built each dummy into a RCA Phono Plug.

I plug the dummies into the SARK by using an adapter from Phono to PL-259.

YES, you should calibrate it.

Hey all,

I'm getting ready to put up a Rohn H50 telescoping mast. The antemnnas that I will be putting on it are a Par OA-50 for 6 meter, a Par OA-144 for 2 meter, a Diamond X50 on top, and a 9:1 Balun Designs balun with a 50-60 foot longwire. Don't have a large enough lot for a longer run. I plan on setting a 4x6x10 treated post 4 feet into the ground with concrete. That would leave 6 feet above ground to bolt the telescoper to. I will be using mast clamps that I got from Penninger Radio to mount the mast. My question is do you all think that will be sturdy enough to work? I won't be able to guy it off as I don't have the room for the lines. Any opinions appreciated.

Paul,

If I'm not mistaken, Rohn requires guying of that mast. That's a fair amount of wind loading at the top combined with the asymmetric force of the longwire. Scares me and I'm fearless...but I'll defer to the experts in this user group.

Paul,

No guys on an H50!

Frankly, my guess it will kink and fold over in the first 20mph wind if it's only attached at 6' off the ground. Top section is probably the leading candidate.

Rule of thumb going up any pipe is a guy wire every 10' (maybe 12'). Yea, yea, I've seen 20ft of pipe with something like an X50 on it but eventually they come down. If you don't have room for guys then I gotta ask... What's it gonna hit when it comes down?

Paul,

Opinions are worthless.
That kind of question needs to be sent to the manufacturer of the mast.
If we all tell you "sure, that should work" and you put it up and it comes down in the first storm, guess who gets hosed!

Also, the hf antenna you are building is pretty lousy. Like buying a Yugo when you need a car. Sure you will be able to load it with a tuner but performance will be marginal.
You have a nice station. The antenna is the most important link in the chain.
If that□s all one can do, then fine. But I□m sure you can do a lot better.

Hey all,

I'm getting ready to put up a Rohn H50 telescoping mast. The antemnnas that I will be putting on it are a Par OA-50 for 6 meter, a Par OA-144 for 2 meter, a Diamond X50 on top, and a 9:1 Balun Designs balun with a 50-60 foot longwire. Don't have a large enough lot for a longer run. I plan on setting a 4x6x10 treated post 4 feet into the ground with concrete. That would leave 6 feet above ground to bolt the telescoper to. I will be using mast clamps that I got from Penninger Radio to mount the mast. My question is do you all think that will be sturdy enough to work? I won't be able to guy it off as I don't have the room for the lines. Any opinions appreciated.

It isnt going to be fully extended. Per Columbus code it cant be over 35 feet high.

I work for a company that manufactures and sells amateur radio antennas and masts internationally.

I get asked that question 2 or 3 times per week.

The answer is in plain English (or German if you prefer): follow the recommended guying instructions.

If someone erects one of our masts lower, we have instructions for that too.

Failure to follow the manufacturer’s guying instructions may result in the insurance company rejecting the claim.

I STRONGLY ADVISE TO CONSULT THE MANUFACTURER and follow his advice.

https://www.dropbox.com/s/ky44kcsqqfha4xz/sark100_package.zip?dl=0

here you will find any thing that i found for the sark100

software, documents etc.

you will find two different windows software

plus command line soft (has to be started with a batch file) that makes csv files that later can be opened with zplots (excel sheet)

(so three different things to try on a win pc)

Plus android software (add a bt module to mini60/sark100 to test swr wire-less) ... that should run on a smart-phone or tablet

greetz

sigi

ps feel free to ask if you have questions

Evan is, of course, correct. Read the Rohn brochure on that mast. It REQUIRES 3 or 4 guys AT 5 LEVELS.. It would never survive unguyed, even without antennas on it. Heck, even Rohn 25 TOWER requires guys when used higher than 35'.

For what you want, you need a freestanding tower, such as BX-48, or something from Heights or Texas Towers or one of the other vendors. A telescoping tubing mast will not do it.

Good luck.

No, it will not work.

What will work is a 20' mast (maybe 25) as the center support for an inverted v. Feed it with ladder line if you want multiple bands. With a good tuner, that will work up through 6m. You could put simple small ground plane for 2m on top of such a mast. If all you can get is 35' of wire horizontally, then it will operate 20-6m, probably even 30m. 40m with poor performance.

I actually have a 160m off center fed dipole that works all the way to 6m. That's another option, locate the mast off center of the antenna and feed it as an OCFD.

Paul, it would be easy enough to get on hf. There are plenty of ways.
But you need to master clear your brain of what you have read in the antenna books or seen at the QTH of 98% of the other hams.

I use lightweight telescoping fiberglass poles for all of my wire antennas.
There are elcheapos which aren't worth 1/10 of their cheap price, then there is the good quality stuff which will last a long time.

You didn't say what bands you are trying to get on.
If it's only 40m and above, then it's a piece of cake.
As an example you might build or buy one of these:
http://www.aerial-51.com/model-404-ul/
With a 40' telescoping fiberglass pole, you can mount it's feedpoint 37' in the air and droop the ends down to about an 8' or 10' level, tied off to anything.
Removing the top two segments of that fiberglass pole puts it at 34'. Within your legal limits.

If you want to get on 80m, here is an antenna that will get you on the air on ALL hf bands from 80 thru 10m:
http://www.dj0ip.de/vertical-antennas/simple-multi-band-vertical/
It is a very good performer on 40 through 10m and works fair on 80m.
You do need a special matchbox for it; probably can't match it on 80 with a auto-tuner.
I use an MFJ-974B. An old Johnson Viking Matchbox will usually work, but you sometimes need to play with feedline lengths to get it to work on all bands.
Again, this antenna works on a 40' telescoping fiberglass pole. I use the poles from Spiderbeam. They are good quality, but not cheap.

You can mount these poles anywhere in the yard, very easily.
I usually just pound a piece of angle iron into the ground and strap the pole to it.
Example: http://www.dj0ip.de/spiderbeam/fiberglass-spiderpole/pole-base-mount/
The one pictured there is actually a 60 ft. pole.
I have an 80m OCFD attached to it.

Of course these won't work with all of your VHF antennas, but they will get you a good signal on hf.

Well the FM on the pole was all tore up so that isn't possible unless it is on the web site. I live in a duplex so any type of tower isn't possible. Had a very nice antenna system at my previous house but lost that due to medical bills and job cut backs. So am

just looking to get something put back up. Columbus, Ohio code says I can have a telescoping tower as long as it isn't over 35 feet and I have to stay back 5 feet from the property line. Was able to get approval from th property owner to do the pole and longwire.

OK, Here's the answer you want...

Yea, It'll work fine. Put it up right after you by that $1M personal liability policy.

Paul, it would be easy enough to get on hf. There are plenty of ways.
But you need to master clear your brain of what you have read in the antenna books or seen at the QTH of 98% of the other hams.

I use lightweight telescoping fiberglass poles for all of my wire antennas.
There are elcheapos which aren’t worth 1/10 of their cheap price, then there is the good quality stuff which will last a long time.

You didn’t say what bands you are trying to get on.
If it’s only 40m and above, then it’s a piece of cake.
As an example you might build or buy one of these:
http://www.aerial-51.com/model-404-ul/
With a 40’ telescoping fiberglass pole, you can mount it’s feedpoint 37’ in the air and droop the ends down to about an 8’ or 10’ level, tied off to anything.
Removing the top two segments of that fiberglass pole puts it at 34’. Within your legal limits.

If you want to get on 80m, here is an antenna that will get you on the air on ALL hf bands from 80 thru 10m:
http://www.dj0ip.de/vertical-antennas/simple-multi-band-vertical/
It is a very good performer on 40 through 10m and works fair on 80m.
You do need a special matchbox for it; probably can't match it on 80 with a auto-tuner.
I use an MFJ-974B. An old Johnson Viking Matchbox will usually work, but you sometimes need to play with feedline lengths to get it to work on all bands.
Again, this antenna works on a 40' telescoping fiberglass pole. I use the poles from Spiderbeam. They are good quality, but not cheap.

You can mount these poles anywhere in the yard, very easily.
I usually just pound a piece of angle iron into the ground and strap the pole to it.
Example: http://www.dj0ip.de/spiderbeam/fiberglass-spiderpole/pole-base-mount/
The one pictured there is actually a 60 ft. pole.
I have an 80m OCFD attached to it.

Of course these won't work with all of your VHF antennas, but they will get you a good signal on hf.

Subject: Re: [SkyWires] Another Antenna Question

Well the FM on the pole was all tore up so that isn't possible unless it is on the web site. I live in a duplex so any type of tower isn't possible. Had a very nice antenna system at my previous house but lost that due to medical bills and job cut backs. So am just looking to get something put back up. Columbus, Ohio code says I can have a telescoping tower as long as it isn't over 35 feet and I have to stay back 5 feet from the property line. Was able to get approval from th property owner to do the pole and longwire.

Thank you Sigi!

Yep, the problem was simply the batteries needing charged...and they took forever to charge, 10-12 hours.

Now that they are charged up it seems to be working fine, my manual Dentron tuner adjusts the SWR and when checked with the rig it is spot on, and if I use the MFJ auto tuner and tune it for a freq and then use the analyzer it agrees with the auto tuner, so it appears it's working fine and it appears it is already calibrated, though I'll probably order the stuff to make the calibration loads anyway for future use.

Now to figure out which pc software...

Hi Sigi,

I'm looking at the SARK 100 package you kindly uploaded for me and I'm trying to figure out what it all is.

Remember, I'm vision impaired so I just may not be seeing / reading something correctly.

Android_soft - this folder contains Android software

Documents - Contains various pics and documents.

Ftdi_driver - Contains the executable USB / Com Port driver for Windows 7/8.

Sark 100_Gerber - I don't know.

SARK100_SwrAnalyzer_BL - I don't know, I think maybe its got something to do with the firmware for the unit?

Sark 100_WIN - Windows software to download data from the analyzer. It appears this will generate an eXcel csv file?

Google translated read_me.txt:
Windows software
if you have created a shortcut on the
desktop then properties ... and the
file name to comport indicate (see
picture) no longer have to manually
adjust the you can if you use BT easy
to create 2 different shortcuts one for
USB and one for BT.

Sark100_win_install - This appears to be another Windows software program to link to the analyzer? It appears different that the one just above?

Terminal - I don't know, it has a bootloader program, so possibly something to do with the units firmware?

WinPCC-Sark100 - Another Windows software program to link to the analyzer?

Z-Plots - DOS based software to link to the analyzer, can create eXcel compatible files.

Google translated read_me.txt:
the file z_plots.bat edit text editor
PCC sark100 (Proggi located in this folder)

-c COM port
-s start frequency
-e end frequency
-t increment (in Hz everything !!!)

-o filename to be saved under the sweep

after you have saved several sweeps ... you can then look with sark100-zpolts.xls, edit, compare multiple (up to 4 different antennas compare on a display)

Thanks!

Steve

Been playing a bit...

Sark100_win_install - actually opens an installer and installs the program to the programs menu. Easy enough to use program, but no way I can see to save the data.

Sark 100_WIN - Looks and functions exactly like the program above, does not install to the programs menu, just click and it runs.

WinPCC-Sark100 - Appears to be the most useful program. It doesn't install either, just runs when you click on it. It allows saving the data. It will export to an eXcel spreadsheet, though the spreadsheet headings are just x and y for most columns.

If you have a sark100 or mini60 and added a bt module to it then you can use the android soft on a smartpone or tablet ... nice for antenna tests on fieldday cause you do not need to carry a pc with you

> Documents - Contains various pics and documents.

In that folder you also will find info how to add bt to sark100/mini60

A picture from sark pcb showing the connections towards bt modulwe etc.

>
> Ftdi_driver - Contains the executable USB / Com Port driver for Windows

>

Yepp ... that is ftdi driver for usb port

> Sark 100_Gerber - I don't know.

Gerber files ... contains the pcb in gerber format (and that is used from many pcb companies for manufacturing pcb) ... not needed for a user but originally the sark was an open source project from a Spanish ham ... and he also developed the pcb and case for the sark ... and those gerber files ...are from his project

>
> SARK100_SwrAnalyzer_BL - I don't know, I think maybe its got something to
> do with the firmware for the unit?

Correct ... bl means bootloader

If you did not buy a unit from china but have a complete homebrewed analyzer ... then you have to get the program inside in some way

> Sark 100_WIN - Windows software to download data from the analyzer. It
> appears this will generate an eXcel csv file?

> USB and one for BT.

This is how you add the used comport to the windows shortcut (so you do not have to select the port manually after start of the soft)

And when you have usb and bt ... just make two different shortcuts on your desktop ... one for usb and the other for bt

> Sark100_win_install - This appears to be another Windows software program
> to link to the analyzer? It appears different that the one just above?

I accidently put that soft two times inside that package ... one is a zipped file and the other is the folder with the soft ready to use

That is why folder name is nearly the same ... sark 100 win and sark100 win install ...

> Terminal - I don't know, it has a bootloader program, so possibly
> something to do with the units firmware?

Correct ... not needed for a user ... just if you have a homebrewed one you need that
> WinPCC-Sark100 - Another Windows software program to link to the analyzer?
>

That is the second win software that I found for the sark ... try out if you more like the first or the second one :-)

> Z-Plots - DOS based software to link to the analyzer, can create eXcel
> compatible files.

Yepp ... that is the dos box software for the sark

You have to edit the batchfile before you can use it

>
> Google translated read_me.txt:
> the file z_plots.bat edit text editor
> PCC sark100 (Proggi located in this folder)
>
> -c COM port
> -s start frequency

>
> after you have saved several sweeps ... you can then look with sark100-
> zpolts.xls, edit, compare multiple (up to 4 different antennas compare on
> a display)

After you made a few sweeps (with different filenames) you can open the saved csv files with the excelsheet (zplots xls) ...why do I like to use the dosbox software is ... it is easy to use (edit batchfile, make a sweep, again edit batchfile ... and so on) ... and I can then later use the stored sweeps with the excel sheet and compare up to four sweeps in one picture

With the win soft above you can not do that (win soft is for life data while dosbox is more for working with the data later)

.... but anyway ... it is best to have all software and use that one that you need in that right moment ... sometimes it is the dosbox soft ... and sometimes it is the win soft

.....

Hope that helps

Greetz

Update on the loop... I have had 1000 foot of wireman solid 14 gauge clad up at 70 feet for about a year now. I fed it with 450 ohm ladder line about 60 feet into a 4:1 dx engineering balun 5kw. From there 15 feet of lmr400 into the shack. In the shack is a palstar hf auto, ameritron 1306, icom 7600... The loop has worked extremely well for me on all bands 160-10m. I was blessed to work VK and JA on the loop (160m) both RX and TX on loop only and 1200w.
Yesterday I took a direct hit to the loop which melted about 90 percent of the ladder line. After investigation, the loop wire is fine, it was the ladder line that was the weak link, maybe to my benefit... I did have the gear unplugged. I have new line on order and hope to have it back on the air soon. I will be moving it a touch further from the house after this strike. Everyone keep it safe out there, large loops can be a pain but worth the results ,

Hi Sigi,

I'm updating my notes -thanks!

Did you know that there the ZPlots spreadsheet is a several versions behind?

It doesn't appear it's customized for the SARK as the new one seems to work for me.

Download the new version here:

AC6LA Software - Zplots http://ac6la.com/zplots1.html

http://ac6la.com/zplots1.html

AC6LA Software - Zplots http://ac6la.com/zplots1.html Buttons available on the various sheets are: Load Data: Read a data file from one of the above...

OK, I think I'm getting the hang of the SARK100 software.

I'm wih Sigi here, I think I like the DOS software invoked by batch files.

I did a sweep of my loop antenna from 160 to 10 meters with .1mhz steps and uploaded it.

Interesting thing here. I'm using a 1:1 tuner balun from Balun Designs. My MFJ auto tuner can find a 1:1 match for every band, including 160, except 15 meter, the best it can do there is 1.5:1. The auto tuner has a built in 4:1 current balun and if I hook the antenna up to it then it finds a 1:1 match on every band.

Man, 1.5:1 is the same as a 1.0:1 as far as performance goes.
Forget it.
If it really bugs you, just add 4’ of openwire feedline to the feedline and try again.
But it’s majoring in minors to try and get it better!

The autotuner's balun may find a 1:1 match on every band, but you might also have common mode current problems when using it. Perhaps not. The 1:1 balun will kill the CMC for sure.

You should also do a sweep with a 1:4 or higher and no tuner ... and with different length of ladderline (and a bit of pruning on the loop??)

I can do a sweep with a 1:1 and with a 1:9 ... and both show low swr spots ... but on different bands

What I use here is also a tuned length of ladderline ... a shorter run from loop to shack ... and another length is added on some bands with just two banana plugs

With that setup I could set my sweet spots exactly where I wanted them (three days of pruning loop and ladderline with several try and error runs ... that was BEFORE I had a sark!!!!)

What I use her is a homebrewed 1:9 ... reason is

I use the ladderline as a transformer ... from low ohms (cause the loop is low in wavelength on the lower bands) up to 400 to 500 ohms and with the balun back down to 50 ohms ... on higher bands the impedance of the big loop is more in the several hundred ohms range and then the ladderline is almost matched (and almost no transforming does happen) ... and so I also have a few hundred ohms on shack end (and with that balun back down to 50)

On most of the bands I do need no tuner at all (or only on band edges)... and on the other bands it is well below 1:3 ... more in the 1:2 range(and so low tuner loss)

I have a large spool of old 2 conductor military communication wire that I tried this with. This is basically ruggedized 16 gauge zip cord.

I put up a 270' piece of wire in a loop about 35 feet high and fed with about 65' of 450 ohm ladder line. The ladder line connects to a 4-1 balun then several feet of coax into the shack. I use a tuner.

Most of my on air tests were done on 80m and not very scientific. I do not have any of my measurements documented, but I might be able to find some 1-30MHZ SWR plots on my old computer of each of the three below.

First: I tried it with both conductors tied together for one 270' loop
-This worked well.

Second: I configured it so each side of the ladder line fed different conductors and did a crossover between the two conductors making two turns of 270'.
-This worked ok but not as well as the single loop.

Third: I cut the crossover and let the ends dangle down a few inches so they were not too close together essentially making a 540' doublet.
-this worked better that both the other two configurations.

Those are my experiences with a single and double turned loop.

I have a 550ft horizontal delta loop and have often wondered the same, if a extra run would help.
What would your spacing be?? Would you run the wires in a parallel setup or series?? Please keep us informed.
Rich, KdØzz

On Thu, Jul 23, 2015 at 11:40 PM, w6mob@... [SkyWires] <SkyWires@yahoogroups.com> wrote:

All

I had good success with modeling and building a 283 feet loop at about 40 feet high.
I remember that for smaller loop, at least, increasing the area and/or the number of turns of wire will improve the voltage across the terminals.
So my question is has anyone tried to use multiple turns or wire? If so what type of results did you see?
I wanted to ask before I go and try to put up 4 or 8 turns of 283 feet all ziptied together.

Cheers

Your 540 doublet was not a doublet but still a 270 loop

Reason ... the close coupling of the wires made it act like one thicker wire

And that is also the reason why the setup with crossover did not work well

You were almost short circuiting your energy

Hi Rick,

Yeah, i wasn't worried about it, just something I noticed.

Hi Sigi,

Thanks for the tips!

Unfortunately I only have the one external balun and since I'm low vision building my own isn't really an option for me any more.

As long as the loop works with my auto tuner I'm happy, and it's been working extermely well! I've worked over 30 countries in the last month or so!

I'm hard pressed to mess iwth success, but I'm looking at moving the feedpoint to a spot that's more asthetically appealing to the wife and while I'm at it I think we'll see if we can get the west end up a little higher in the second tree (we had it higher but it slipped off a branch and the wind that day was strong enough that reshooting was an option). Hopefully the mods don't cause any issues!

Take care, thanks for the input and the SARK100 help!!!

73s,

Steve

Jay. Glad your strike wasn't any worse than it was. Especially you health and safety. Lightening is SO unpredictable.

Evan. If you see this, what quick disconnect do you use. I've always disconnected all my coax fed equipment and all power cables when my equipment isn't in use. Would be interested in installing some kind of disconnect outside as well.

On that topic, has anyone tried using the biggest set of Anderson PowerPole connectors.

Seems they would be ideal – mounted separately of course, not side by side.

Paul I use the Molex connects from Radio shack , same ones that are on the back of the Icom radios for the antenna tuner... I have used them for a year, once an awhile you have to squeeze the female connector a little closed but they have worked fine for me and the 2 outside connectors are just about right spacing for 450 ohm line... I have new stuff ordered to repair my antenna, and This time I am moving it about 8 feet from the house, and when not in use I will have another Molex plug straight to a ground rod... My thought is the only way to be safe is to disconnect and move the feed into the house as far away as possible...

I just use banana plugs (and sockets) ... if contacts become bad I replace them with new ones ... reliable and cheap ... and if something hits your antenna wire (no not a strike ... I mean mechanical).. then the bananas pull out without any damage ... works fine here

And if you also have some connectors at your ground rod before house entrance ... then it is easy to connect the ladderline to ground OUTSIDE of the house

I do not know if grounding does the strike move towards your house (but I have heard that strikes love grounded metal structures in the air) :-)

Better keep that high power out of your house

My system uses banana plugs and jacks BUT the higher priced ones with nickel plating to resist rust. They are in a weatherproof enclosure and I've not had any failures in almost 10 years of use. The terminals are mounted to a speaker plate that is used to make connections with hi-fi installations. I've used this at legal limit power levels and have not had any failures or problems and it is very quick to disconnect or reconnect.

Does anyone know what power plug size the Mini60 needs?

The specs say it's a 2.1mm center pin and that usually just comes with a 5.5mm outter barrel, so that's what I ordered and the outter barrel is too big and it won't fit in the hole.

It looks like the standard smaller diameter sizes are:
4.8 X 1.7mm
4.0 X 1.7mm
3.5 X 1.35mm

5063. DC Power distribution in the shack

I'm looking at a nice way to handle DC power distribution in the shack and I'd like to have quick disconnects, I see MFJ makes a DC power strip that uses banana jacks but I'm using banana jacks on my ladder line and you can plug banana jacks in wrong. I'm not worried about myself, but I'm low vision and they don't know the cause of my problem, so can't guarantee it won't get worse so others may be plugging and unplugging my stuff in the future, so I want to make things idiot proof.

.

What I want is a power strip with plugs that can't be plugged in wrong...I'm thinking a regular a/c power strip is what I want, but again - I want it idiot proof, so diverting one to DC use isn't a good idea...but what about a foreign power strip? Maybe a European or Australian one?

.

Anyone done anything like this, or how do the majority handle DC power distribution?

.

If worse comes to worse, ti doesn't have to be quick disconnect, I could probably get by fine with a simple screw type terminal strip, but quick disconnect is just really nice.

.

Looking forward to hearing about what others use.

.

Anderson power poles (just google them)

There are similar power strips that you have seen with banana plugs
available that have these wonderful Anderson connectors instead of banana
plugs ... (if I remember right I also have seen a combined one with BOTH
connectors ontop)

An few examples here

http://briandorey.com/post/powerpole-fused-distribution-board.aspx

http://www.powerwerx.com/powerpole-power-distribution/rigrunner-4005h-horizo
ntal.html

http://www.westmountainradio.com/rigrunner.php

etc. etc.

you will find a dozen different solutions with these Anderson connectors

and ... they are foolproof :-)

Yep - Power Poles are the way to do this. Red positive, black negative, cheap, you can likely get premade power cords for your radios with PowerPoles on them. They won't plug in backwards, they're low loss, high current, great connectors.

MFJ has good powerpole stuff, as does powerwerx:
http://www.powerwerx.com/

5076. DX Spotting

Yahoo group: SkyWires
Date: 2015-08-08 23:37:06 UTC
From: slr_65@...
Topic: 5076 Message: 5076

I've been using DXSummit to help locate DX. I like it, but I wish it had more configurable filters. i.e I'd like to be able to just see spots in the general class portion of the band, spots only reported by US stations, etc..

I know there's a lot of software out there for spotting, but I'm low vision and reading up and researching it all is hard and has my head swimming...save me some time, what do you guys use?

73s,

Steve, KA)NEB

Forsale: Icom IC 7800 & ICOM IC 756 PRO 3 with ICOM PS 125.

Callsign: KJ6DBP
Email: kj6dbp@usa.com

Icom IC-7800 Low usage in Non Smoking Environment.
This rig has always been covered when not in use.
The rig is in mint as new condition.

Icom IC-7800 version 2 with 3 Roofing filters (15,6 & 3 kHz) and current 3.10 firmware.

Also included:
Icom SP-20 Speaker
Heil PR 780 dynamic cardioid microphone
Heil Pro Set iC boom/mic/headset combo
Heil HMM-iC hand mic
Heil HS-2 hand switch
Heil CB-1 mic base stand

$4,350 and you'll pay the shipping fee.

ICOM IC 756 PRO 3 and ICOM PS 125 matching Power Supply for sale.
Also Included:
Icom Manual, Power cord, Nifty Mini Manual, Icom HM 36 had mike and original brochure.
This radio is in excellent condition, has lived in a non smoking household and has no repairs and or modifications. I am the original owner.

$1,300 and you'll pay the shipping fee.

Look at DXLAB suiteIt is free and offers anything you would want to do.yahoo group available the spotter is called spot collectorYou use other parts of suite that will put you on DX. freq. with mouse click.You can setup to only spot a band all bands, spot all modes are just one.If looking for a particular dx station or country,
you can setup for voice alarm to to let you know.Hope this helps73 John K5JRW

5084. JSX Array

Yahoo group: SkyWires
Date: 2015-10-03 21:09:12 UTC
From: n6jsx@...
Topic: 5084 Message: 5084

I was going to make a big 160m loop until I got an epiphany of how to make it much better. Fist since YGroups does not allow diagrams to these posts let me explain what I'm up too.

I live in the country (on a lot sliced off a farmers field). I am putting up four ~30' towers (free standing) on basically the corners of my lot to just hold wires. The array will be near 200' square with my home in the middle and coincidentally a 30' TV tower almost directly in the middle of this square. Since my lot is north-south the towers will be in the NE/NW/SE/SW corners.

My initial intention was to put up a 160m full wave square loop using 450-ladder line feed - my intent was to make it an all-band loop using my roller-L tuner. But a few weeks ago I had an epiphany that should give me a much improved directivity if instead I make four 160m quarter-wave elements from the center tower and select what element would be connected to give me a four direction V-Beams or two-Dipoles. V-Beams will be due N/S/E/W and dipole NW-SE & NE-SW. I intend to use 33' of 450-ladder from the tower top controller to the base connect to an UglyBalun (RF choke) to coax into the house/shack to the tuner.

The trick is making a four-antenna wire tower mounted controller. At first this seems like a no brain'er until you start looking at the details of this controller and taking into account safety, parasitic radiation, ESD/lightening, etc. At present it looks like I'll need three sets of four relays DPDT.
First, four-relay set to select-connect an element to one side of the feedline;
Second, four-relay set to select-connect the other element to the feedline;
however, when each of these select relays are made I want to insure the same element cannot be shorted to the feedline.
Third, four-relay set to allow float or ground switching of the unused elements;
than a single relay at the feed to flip the elements to the feedline just to see if any cause-n-affect.
Ya it gets complex which also means I need to run a multi-conductor cable up to the tower controller and I'm likely to design a PCB to simplify the wiring. The Base controller will have banks for relay control switches and LED's to indicate what is HOT-connected, all this will be using 12VDC. The fun of electronics-HAMdom.

I've searched for anyone else who has made a similar array to nothing on the web. I've been researching my extensive Antenna library and cannot find the answers I seek.

My questions are:
1. When the array is not in use should I float all wires (minimize lightening leaders and ESD hits)?
2. When using two elements for a V-Beam or Dipole should the other unused elements (in the same RF plane) be grounded or floating? Will they pose parasitic radiation concerns messing up the active element VSWR?

Please if you're going to answer - give a sound reason for your answer, not just hear-say. Thanks

What band(s) are you going to use this on? You say a 160m loop, if your prime interest is 160 (or even 80m), your height (30') and shortness of the v-beams will cancel any directivity. And the 90 degree +/- angle is too wide for much directivity on the higher bands were the wire length might start to get long enough to be useful. Study the antenna books to see how long and how high you need a vee beam to be useful.

My personal experience, I started out with a 700' loop, had great difficulty loading it on 160 and 80, cut it down to 500', a bit better but still a major effort. It did not perform any better than a 160m inverted vee. Finally, I cut it down to a 160m OCFD which loads easily on all bands 160-6 and does well.

Whether one puts up an array of verticals, horizontal loop, etc. the first question should be, "What are my goals?" Is stateside coverage most important? DX? Both? To me, a horizontal loop and a 4-square, or whatever other antennas are considered, can't be compared directly unless one knows what parameters one is trying to optimize, or minimize for that matter. For example, reducing noise (via a horizontal loop) requires a different approach than trying to direct the RF energy toward a particular country (via a 4-square array, beam, etc.).

Having said that, and having used vertical antennas for years (but currently use only horizontal loops) as well as inverted L antennas, I've found that connecting an RF choke between the element and ground, or a high value carbon resistor(s) in the 100K to 200K range, will bleed off static electricity that builds up due to wind, blowing snow, etc. No, it does not afford protection against a direct lightening strike and that's why I disconnected the coax where it enters the house and moved it 15 ft away when storms approached or during long periods of inactivity.

Unfortunately, I can't provide any sound experimental research findings to support the basis for the above. I merely drew upon the experience of others (LB Cebik, ARRL, etc.) and proceeded accordingly.

A standard one wave length loop works very well, so why deviate from what works. I have posted in the file section, an article about my 80 meter loop. It covers all bands 80 through 6 meter, with the exception of 60 meters. I feed it with coax and any of my rigs with a built antenna tuner will tune it. It works great for stateside and DX.

5091. Affects of tilting the loop?

Yahoo group: SkyWires
Date: 2015-10-23 19:28:45 UTC
From: slr_65@...
Topic: 5091 Message: 5091

Hi Guys,

Been a while...I had a heart attack and it's been an adventure, I have a tendancy to flat line (happened once during stent install, and two other occasions following stent install during recovery!)!

I feeling much better though.

My loop is strung in the trees, is about 210' in circumference and is tilted from about 12' to about 45'. The south end is the high end, it's fed in the middle of the low end on the north.

It works DX wonderfully! Especially central Europe, I'm almost tired of talking to Croatia, Slovenia, etc.! It also goes to the south pacific easily, I can work Hawaii, the Cook Islands, New Zealand and Australia most any time I hear them.

A friend lives just a block away, he strung a loop in the trees too, but he was able to keep the loop horizontal. He's a bit longer than mine too, probably 325' or so in the loop.

I run a Kenwood TS-590SG and a MFJ-993b auto tuner. He runs a Yaesu FT-101EE and an MFJ manual tuner. My rig hits 100 watts on the nose, his runs about 120, shouldn't be much difference on the other end.

I can get out much better, in fact yesterday he got frustrated trying to work a Brazillian station, called me on the repeater and I gave it shot...first try I made it 59.

I realize my speech processor and stuff probably keeps a little more average power, but still, I would think he should be a bit more successful as this isn't the first instance. I don't mean to make sound like he doesn't get out, he does, but it seems I do better, wattage is essentially the same, so I'm wondering if it's the old vs new equipment, or because my loop is tilted, or "just is"?

I've thought about toosing a loop essentially vertically over my trees just to see what it does, but then I thought that this experiment has surely been ran, so I'll just ask!

Steve,

Glad you are still with us! I'm just waiting on having my application to the Silent Key Club approved.

If I understand the two antenna configurations, slope alone of the horizontal loop would not account for the differences. Why? Well, your antenna is tilted to the north, Brazil is to the south. Slope does affect the radiation pattern, more so as the antenna frequency goes up. In fact, slope can improve radiation pattern toward the direction of the slope as one goes higher in frequency depending on conditions; as the frequency is increased, there can be more penetration/absorption of the ionosphere as the angle approaches 90 deg where as a shallower angle might see a little more reflection than absorption/penetration. These are vague generalizations based upon limited research and I've not found a truly credible, physics based source yet.

There might be some site specifics at work here, equipment factors, etc. Since you didn't mention the height of his antenna, there is no way to compare the two antennas by going to the modeling research for answers. It is even possible that his antenna has a lower angle of radiation than yours and thus might not have favored Brazil on that single test.

Hopefully the experts will chime in and provide some guidance. I'm always eager to learn.

73,

Evan, K9SQG

PS In addition to knowing the height of the other fellow's antenna, it would be interesting to know what band you're on in order to put things in perspective in terms of wavelength above local terrain.

Hi Evan,

LOL! Yeah, I'm hoping my app for the SK club is on hold for a bit too!

The other antenna is horizontal at about 40', we've only played on 10 meter because he's a Tech.

I continue to be amazed at how well my loop works, in the CQ contest over the weekend I logged 55 DX entities and I was busy with other things and didn't get to spend as much time at it as I wanted to!

5095. Logging software

From: slr_65@...
Topic: 5095 Message: 5095

Hi Guys,

I'm using QRZ's log right now, mostly because being a web page it gets along very well with my high contrast color scheme needs for my poor vision.

It doesn't export to cabrillo though (though it does to adif), and it doesn't interface to the rig or anything.

I can deal with QRZ for normal casual use, but for contesting I think I'd like something better.

What do you guys use?

73s,

Steve, KA0NEB

There are a lot of factors to consider such as; height above ground, ground conductivity, obstructions, etc. But, that said, a vertically polarized antenna generally has a lower take-off angle than horz. My 80 meter full size delta loop in a 110' pine tree is tilted at approximately 45 degrees with the projected lobes aimed at Europe (using antenna modeling software). The lower wire is 60' high and the antenna is fed about 1/3rd up a 45 degree side with 450 ohm ladder line to a 1:1 current balum with two foot of coax into my tuner. It is a DX beast on 40 meters and sometimes outperforms my tribander on the higher bands. The sides are different lengths since I used existing pine trees for tie-downs. It helps that I am on top of a 1800 foot hill.

Hmmmm, at that height, and 10 M, things start getting strange. I'd encourage you to look at the horizontal and vertical propagation plots for your/his antennas. They can be found in L. B. Cebik's book sold by MFJ, on his website, and possibly online.

Like you, I enjoy my horizontal loop antennas (one an 80 meter variant and the other a 40 meter model). The 1-2 S unit reduction in noise is well worth it.

Have a great week!

Hi Richard, I've tried Log4OM, but it doesn't get along with the high contrast color scheme I need. I may contact the author though, most of the time it's not too difficult to add a little more appearance control in, and when you can talk directly to the author you get answers, and hopefully results, much faster than with large commercial software.

Apparently software developers don't always research the topic to find "forbidden color combinations" nor "preferred color combinations" and thus produce an interface along the lines of "Well, I can use it, therefore it is usable." Nobody ever accused developers of adhering to usability standards or preferred practices for ham radio software or equipment.

I'll see what I can find Evan, but book reading is hard for me. PDF if it's OCR'd is good as I can flip to white text on black background, scanned ones are hard, I have to extract the images adn flip their collors with a graphics program. Actual books I just gotta tough it out with a bright light and a magnifier, but I usually avoid that.

Probably waaay to manh variables to get a handle on it. It's a really odd shape as it's just tossed through the trees, plus all the other variables.

It does well though! His loop is longer and encompasses more area though, so I would expect it to do as well, if not better, but it doesn't seem to, this isn't an isolated incident, it happens a lot, but it may be related to the other equipment or something - his Yaesu does't have a speech processor or anything, so his average power is less, his audio sounds fine here - the few times we've qso'd on hf (usually we'd just UHF it or just walk down the street, LOL!), but perhaps at a distance it may sound different.

Who knows, it's interesting that verticals have a lower take off angle, I may try tossing a wire over the two trees vertically and see what it does just for something to do.

Good to hear from everyone, it's GREAT to be feeling better and radio playing again! I didn't think I was quite ready to take my Extra test, but a buddy wanted to take his General and wanted company, so I went anyway...I'm glad I did! The Extra bands were hopping during the contest!

73s,

Steve

Steve,

Congratulations on your licensing and antenna experiments.

And on the topic of antennas, I'd say give them the test of time and see how things work out. Isolated observations don't yield much insight about RF patterns, hi hi. Regardless of what online research would indicate, there are always site specific things than can alter experiences.

73,

Evan

☐Good old tuner☐ is pretty meaningless.

It all depends on just how good it is.

There is of course never any such thing as ☐best☐ of anything.

It☐s always horses for courses.

What works well is a long wire that is ½ wavelength on the lowest frequency to be used.

But of course it is very high impedance and requires a matchbox that can handle very high voltage.

The best matchbox for that specific antenna is an L-Network.

The advantage of the hal fwavelength rather than the quarter wavelength is that it can be very efficient with just a single wire counterpoise (quarter wavelength), whereas a quarter wavelength, though easier to match, requires a good radial network to be efficient.

You might start by telling us what your tuner actually is.

Yes, the table on that link is good if you do not have a really good tuner… which few people have when it comes to matching long wires.

John,

The various antenna books list some "best to avoid" lengths but they are only very coarse guidelines. Why? Part of the issue is the downlead from the long wire which becomes part of the total antenna length. Also, long wires are prone to matching problems since they are typically high impedance, sometimes very high, and also may have RF in the shack problems. It is usually advisable to have a good ground attached to the antenna tuner to minimize such issues. Too, if one wants to be creative, traps can be installed in the long wire to make it "appropriate" length for the various bands.

Glad to see you're staying on the air! This is a great hobby that we have.

73,

Evan, K9SQG

Subject: [SkyWires] Best long wire lenths

Hi All settingup an alternate statioln as Im currently Bed bound most of the time. I was wondering what (IF any the recomended Long wire lenghts would be for mostly 40/80/(160 Sometimes) I have a good old tuner and a ts680 to help with tall this. Not looking to do gand busters. Just check into Ecars/mid cars during the day. Perhaps OMISS and CCN inthe evening. thanks for any help!

"Good old tuner" is pretty meaningless.

It all depends on just how good it is.

There is of course never any such thing as "best" of anything.

It's always horses for courses.

What works well is a long wire that is ½ wavelength on the lowest frequency to be used.

But of course it is very high impedance and requires a matchbox that can handle very high voltage.

The best matchbox for that specific antenna is an L-Network.

The advantage of the hal fwavelength rather than the quarter wavelength is that it can be very efficient with just a single wire counterpoise (quarter wavelength), whereas a quarter wavelength, though easier to match, requires a good radial network to be efficient.

You might start by telling us what your tuner actually is.

Any reason you don☐t just answer the question?
What tuner is it.

While you have some time on your hands, you might want to read up on antenna theory.
We have a double-edge sword here with the longwire antenna.
What works best as a radiator is quite a challenge for most antenna tuners.

Recommended long wire lengths found in many online lists are often chosen based on their ease of being matched with lesser matchboxes ☐ not by their ability to radiate efficiently.

If your tuner is good enough, the half wavelength is the best length.
If not, then you must avoid this length, as has been recommended by others.

At the end of the day, everything works, as long as your matchbox will match it.

A good rating on review sites in not really very meaningful.
Most people don't understand matchboxes well enough to rate them.
If they did, they wouldn't call them antenna tuners!

In any case I wish you a speedy recovery.

OK John,

There was no 944 matchbox but there were various 94x tuners (i.e., 941, 945, etc.), all basically the same circuit, with just features making the difference.

Basically these were (and still are) T-Network matchboxes with a □moderate□ matching range.
They use 208pF for each of the capacitors.
This would not be enough to match the impedance of a half wavelength wire, so it will be important to avoid the half wavelength.
If you can be about 1/16 to 1/8 wavelength away from the half wavelength length (preferably longer, otherwise less), then you will have no problem matching with this matchbox.

Efficiency will be down a little but probably only cost about one S-Unit. This can of course be avoided if you put down several radials but that is probably not an option.

Regardless of what length you choose, you MUST use a counterpoise. The counterpoise can be simply ¼ wavelength of wire for the lowest band that you plan to use.
Under the circumstances, you should probably pass on 160m.

¼ wavelength on 80m is about 66 ft. You have to run this wire somewhere. It should be insulated wire (not bare copper), attach to the ground terminal of the matchbox and then run along the ground (back out the window then along the ground, etc. However if you are upstairs in the house, you may need to run it inside the house. That□s a lot of wire for inside the house. It can run zig-zag, around corners, etc. How and where doesn□t matter; the length does. It needs to be 66 ft. long for 80m or 33 ft. long for 40m.

The antenna I was referring to earlier is what I ran while going to college (U. of Florida) back in the 60□s.
I was very active as net control station in the National Traffic System with this antenna.

The old WRL Antenna Matchbox I used had a single coil and a single capacitor but the capacitor was at least 500 pf.
800pF would be better for this task. This is what is needed for matching half wavelength wires. But then they go like a house on fire!

As I understand it, the main task is to just get on the air on several bands. In that case, just about anything works.
Don□t forget to tune the matchbox at reduced power (20w or so), then AFTER finding the match, increase power.

Gud luk with the antenna.
Sorry I can☐t be there to help you, but Lufthansa is currently on strike!
;-)

I've had good results using a 9:1 UNUN with a 124.5 foot sloping wire as described at the Balun Designs web site:

http://tinyurl.com/o7kuh4j

-

This configuration requires a counterpoise wire or wires for best results and works well on all bands from 160m to 6m, yet doesn't take up a great amount of real estate.

Bill,

Please define “good results”.

Did you run any A/B tests and compare it to other antennas?

I only tried the 9:1 balun once, had a single counterpoise laying on the ground.

In the A/B tests compared to a trap dipole for 80/40/20, the LW was always 2 to 4 S-Units worse.

It’s a fair antenna if the goal is to just get on a bunch of bands and you need a decent SWR.

But if you want a good signal, you can certainly do a lot better than that.

There is no mystery around this stuff.

Efficiency (%) = (RR / (RR + RG)) x 100

RR = radiation resistance

RG = ground resistance

Of course there is a 3rd resistive component, the resistance of the wire itself and theoretically it should be considered but it is so trivial compared to RR and RG that there’s no need to bother.

Good question.

Very few people are able to measure ground resistance.

There have been a few documents published explaining how it can be done, but it is WAY beyond the means of most people.

Radiation resistance for popular antennas is known.

A halfwave dipole in theory has 72 ohms.

A quarter wave vertical has half that, or 36 Ohms.

The ground resistance is what it is and we can’t really change it… unless we lay down a lot of radials.

Let’s say it’s 20 Ohms, a not so untypical value.

In theory the efficiency would be (36/36+20) x 100 = 64%

You can measure the antenna with a simple antenna analyzer.

It will show you the impedance, expressed in Ohms + Reactance (either capacitive or inductive).

For instance it might read 25 Ohms –j125 .

The 25 Ohms is the restive portion of the antenna.

This can of course be measured with your AIM.

But I don’t really know what to tell you about measuring ground resistance.

In any case, the higher the radiation resistance, the less negative impact the influence of ground resistance will have.

Or, stated another way, the lower the radiation resistance, the higher the need to improve the ground with radials.

If you have the room, I find it easier to extend the length of the wire in air than to lay down a bunch of radials.

But then you need a matchbox that will cope with the resulting high voltage.

5118. Evaluating an antenna

Yahoo group: SkyWires
Date: 2015-11-17 23:35:22 UTC
From: kl7rs@...
Topic: 5118 Message: 5118

I'd like to make a suggestion to the group. When evaluating or reporting on a particular antenna, please try to refrain from saying how good the antenna is unless you are able to compare it to another reference antenna through the use of a simple A/B switch.

The internet is full of people praising an antenna while never comparing it to anything else through the use of a simple A/B switch. Some folks will say something like - "This new antenna does way better than the one I had up 3 months ago". Or "I can talk to everyone I can hear" or "signals seem louder" or "swr is flat across the bands", or "I had a qso with a guy in Brazil last night". This is meaningless dribble.

Short of using expensive rf measuring equipment, one of the best and inexpensive way I have found to tell how well an antenna works is by immediately comparing it with another antenna using a simple A/B switch. This comparison is done during the same exact conditions and revels a lot about an antennas performance and characteristics.

If you want to try a new antenna design, I highly suggest you leave your present antenna in place. If you don't have a present antenna, at least put up a simple dipole or vertical. Next, put up the new antenna as clear from the original / reference antenna as possible. Sometimes this is hard and the two antennas end up being pretty close. So what, you will still get a reasonable comparison. Run both antennas into a A/B switch and try switching back and forth between the two antennas during QSOs over the course of several days and nights. Even using this method, it doesn't tell you that the antenna is good or not, it just tells you weather it is better, the same or worse than your dipole or what ever reference antenna your comparing it to.

You'll be amazed at how well this method works and how much you'll learn from the process. Besides, its also lots of fun! Since this was explained to me, I have always tried to have at least one reference antenna in the air at all times. Lots of us are limited in space. I know - I have a small lot and also live in an HOA which is even more of a reason to strive to have the most efficient antenna you can under the given circumstances.

Lets say you have a vertical antenna and your using it as your reference antenna. Your main antenna is a standard center fed dipole but your thinking of replacing it with a OCF dipole but you don't have enough room to run both at the same time. First you make a bunch of TX / RX comparisons between your center fed dipole and your vertical. Night, day, dx, local, etc. Write down the comparisons. Example, Lets say that on 20 m when talking with a friend in Chicago during the afternoon, the dipole pretty consistently about 1 S unit stronger than the vertical on both TX and RX. Next, take down the center fed dipole and put up the OCF in its place. Now make another comparison with your friend in Chicago on 20 m in the afternoon. Switch between the vertical and the OCF. Now lets say you notice that the OCF is giving you about 2 s units better signal than the vertical. Well, simple math says its about 1 s unit better than the center fed dipole. Now you really know something. You have some actual data to backup your hunch that the OCF may be a better antenna than what you were previously using. To be sure of this, you'll have to make these comparisons over the course of several days and nights and on all of the bands you normally operate on. You'll now have some data that you can go back and look at if you ever decide to try to improve on

the OCF and maybe replace it with a loop, zep, double zep, G5RV, ZS6BKW, long wire, etc....

Better yet, publish comparisons on any antennas your testing. This type of information is really worth sharing and I'm pretty sure everyone in the group will enjoy it. When you do post your comparisons, make sure you include particulars on both the reference antenna and the one your testing. You'll want to include things like how high it is, orientation, material its made of, lengths of radiators, number and length of radials, frequencies of comparisons, and of course the difference in TX and RX signal strengths you've recorded.

Just saying "I tried antenna X and it seems to work real well", is pretty meaningless.

5120. RE: [SkyWires] Evaluating an antenna

Topic: 5118 Message: 5120

OUTSTANDING post Norm,

Thanks for suggesting this.

The only thing I would add is that 40m is a bit different.
It is not one band, it is 3 bands. Perhaps 4.
That's because the difference in its performance during daytime operation and night time operation is as different as, well, night and day. But there is more to it than that. We have dawn and dusk.

1. Daytime, 40m is a great NIVS band for working local friends

2. Night time, 40m is a great DX band and you can easily work the entire world on this band if you have a good antenna.

3. Dawn and dusk (grey time), 40m behaves much different. You can often work both NVIS and DX at the same time. The angle that the DX signals are arriving changes rapidly and during A/B tests, you sometimes see both antennas being better and worse, every 10 to 20 seconds.

My point: especially on 40m, it is very important to record exactly the time of day and if its early morning or evening, time of year is interesting. For instance it's 7:30 AM here right now and dark as can be. Yet two months ago it was broad daylight at this time.

I can show you a couple examples of what Norm was referring to. They are on my web.

I've done this a few times and sometimes recorded hundreds of QSOs or at least SWL reports. I currently only have two such tests posted. They were over a very controversial antenna.

I'm still looking for the file that has extensive data from a magnetic loop test.
If I ever find it, I will post it here too.

See: http://www.dj0ip.de/antenna-tests/80m-eh-antenna/

Subject: [SkyWires] Evaluating an antenna

I'd like to make a suggestion to the group. When evaluating or reporting on a particular antenna, please try to refrain from saying how good the antenna is unless you are able to compare it to another reference antenna through the use of a simple A/B switch.

The internet is full of people praising an antenna while never comparing it to anything else through the use of a simple A/B switch. Some folks will say something like - "This new antenna does way better than the one I had up 3 months ago". Or "I can talk to everyone I

can hear" or "signals seem louder" or "swr is flat across the bands", or "I had a qso with a guy in Brazil last night". This is meaningless dribble.

Short of using expensive rf measuring equipment, one of the best and inexpensive way I have found to tell how well an antenna works is by immediately comparing it with another antenna using a simple A/B switch. This comparison is done during the same exact conditions and revels a lot about an antennas performance and characteristics.

If you want to try a new antenna design, I highly suggest you leave your present antenna in place. If you don't have a present antenna, at least put up a simple dipole or vertical. Next, put up the new antenna as clear from the original / reference antenna as possible. Sometimes this is hard and the two antennas end up being pretty close. So what, you will still get a reasonable comparison. Run both antennas into a A/B switch and try switching back and forth between the two antennas during QSOs over the course of several days and nights. Even using this method, it doesn't tell you that the antenna is good or not, it just tells you weather it is better, the same or worse than your dipole or what ever reference antenna your comparing it to.

You'll be amazed at how well this method works and how much you'll learn from the process. Besides, its also lots of fun! Since this was explained to me, I have always tried to have at least one reference antenna in the air at all times. Lots of us are limited in space. I know - I have a small lot and also live in an HOA which is even more of a reason to strive to have the most efficient antenna you can under the given circumstances.

Lets say you have a vertical antenna and your using it as your reference antenna. Your main antenna is a standard center fed dipole but your thinking of replacing it with a OCF dipole but you don't have enough room to run both at the same time. First you make a bunch of TX / RX comparisons between your center fed dipole and your vertical. Night, day, dx, local, etc. Write down the comparisons. Example, Lets say that on 20 m when talking with a friend in Chicago during the afternoon, the dipole pretty consistently about 1 S unit stronger than the vertical on both TX and RX. Next, take down the center fed dipole and put up the OCF in its place. Now make another comparison with your friend in Chicago on 20 m in the afternoon. Switch between the vertical and the OCF. Now lets say you notice that the OCF is giving you about 2 s units better signal than the vertical. Well, simple math says its about 1 s unit better than the center fed dipole. Now you really know something. You have some actual data to backup your hunch that the OCF may be a better antenna than what you were previously using. To be sure of this, you'll have to make these comparisons over the course of several days and nights and on all of the bands you normally operate on. You'll now have some data that you can go back and look at if you ever decide to try to improve on the OCF and maybe replace it with a loop, zep, double zep, G5RV, ZS6BKW, long wire, etc....

Better yet, publish comparisons on any antennas your testing. This type of information is really worth sharing and I'm pretty sure everyone in the group will enjoy it. When you do post your comparisons, make sure you include particulars on both the reference antenna and the one your testing. You'll want to include things like how high it is, orientation, material its made of, lengths of radiators, number and length of radials, frequencies of comparisons, and of course the difference in TX and RX signal strengths you've recorded.

Just saying "I tried antenna X and it seems to work real well", is pretty meaningless.

Hi Bob,

Well it’s not a chart, it’s a moving pattern.
It moves 24 hours per day, and it’s size and shape changes every single day by just a tiny bit.

Most of the common contesting logging programs has this feature integrated.
I log with Win-Test.
When it starts to get dusk, I click the Icon and see the grey line pattern so I know which way to turn my 40m beam.
Doesn’t help me much though, because I don’t have a 40m beam. (hi)

It’s simply amazing the amount of software propagation tools available now days.
Makes me wonder how I ever worked so many countries back in the days before we all had computers!

Thanks for sharing the link Bob.
I hadn’t seen this one before.

There are a bunch of software apps out there that show you grey line. If I remember correctly, HRD does this as well.

Hello Rick

Just sent you a prediction software that is very useful (via direct mail)

Try it out

You easy can see at what time propagation goes where (and where terminator/greyline is etc.)

You even can do a prediction of signal level (if you know antenna gain and transmitted power)

5130. Multi-band Horizontal Loop - No Tuner

Yahoo group: SkyWires

I've been all over the internet reading about Horizontal Loops. Geeze there is a lot of information out there.

What I'm looking for is reliable and acurate information regarding the construction of a multi-band loop that does not require a tuner. If this is possible?

This depends a lot on your radio.
If you have one of those Japanese specials that folds back power beginning at 1.5:1 SWR, then you are out of luck.

If you have a really good radio, such as any Ten-Tec, it will play at 100w into a 3:1 SWR all day long WITHOUT folding back power. Then your chances are very good.

However the one I'm thinking of was erected pretty much in the clear.
If I recall correctly, yours runs around your house. Don't know how much that would affect it.

The specialist on this is Everett, N4CY (formerly N8CNP)
I have some info on my web:

The loop that Rick mentions and you will find in the files section, works well with the my Icom 7600 built in antenna tuner and my K3S built in antenna tuner. I am able to use it on 80 through 6 meters, with the exception of 60 meters. My loop is strung between trees in my back yard and is the best wire antenna I have ever had.

I use a similar loop, about 580' that resonates amost idetically to the one on DJ0IP's web site, except lower on each band. At some point, I'm going to go lop off another 5 feet, but it's working so well I hate to mess with it.

It somewhat depends on what multi-band means versus all band. Loops are no different than any other antenna in that they don't work all bands, every band, full bandwidth on each band, 1:1 SWR across the bands, excellent for local and DX, and requires no tuner. Many ads seem to imply that but, actual experiences, not so much. A lot of time can indeed be spent pursuing the Holy Grail of antennas...

I've found that the articles and books by L. B. Cebik (SK, W4RNL) give ample information about horizontal loop antennas. The data support the notion that an antenna tuner is warranted, usually an external one since the built-in tuners in the rigs cannot handle anything more than a slight mismatch presented by a linear amplifier with an untuned input.

But let's see what the experts say...

I have a delta shaped loop, started out with a 500ft roll of 12ga, added about 50ft and adjusted size to a 1 to1 SWR in the middle of the 40M band.
Radio a Kenwood 590
4:1 homemade dual core balun at feed point and RG-8 to radio
Radio tunes fine on 160 thru 40, in use 2 yr
For 20 thru 6m , I use a NA4RR hex beam
I would recommend a delta loop about 80M size w/ 4:1 balun for no tuner at all. Going to 160 size it gets hard to cover the multiples of lengths.
I used a 80M delta loop size for all bands before I added the hex beam.
Here is a chart of SWR readings on my 80M size delta loop
http://i1102.photobucket.com/albums/g453/KD0ZZ/80MLoop_zpsa6e4cfe7.jpeg
When I built my 80M size loop I aimed for the center of 20M, here is a chart of different lengths and shows why a 80M antenna works on several bands
http://i1102.photobucket.com/albums/g453/KD0ZZ/Loop_zps75e5682a.jpg

5137. Horizontal Receiving Loop Questions From A Newbie

Yahoo group: SkyWires
Date: 2016-01-30 06:21:54 UTC
From: deanbianco@...
Topic: 5137 Message: 5137

I plan on installing a large-sized Horizontal Loop as my primary receive-only antenna. Total length of the loop will be roughly 550 feet long. Frequency range of interest is 150 Khz to 30MHz. I want omni-directionality overall. I REQUIRE the lowest man-made noise reduction possible. The height will vary a bit along its length, but I am going to aim for an overall height of 25-30 feet. I will feed it with either 50 ohm or 72 ohm coax. A balun is under consideration, but I lack the proper knowledge here, so:

1. Is a delta loop just as effective as a square? Does one have an advantage over the other? If a delta or a square options become logistically unfeasible for my particular installation (location of the tree supports are going to be a challenge), will an odd-shape work, i.e., a five-sided shape to take advantage of an irregular lot size? Or will this last option seriously degrade performance?

2. What ratio balun should be used? I have seen in my searches values all over the map!! 2:1, 1:1, 10:1, 12:1, 2.5:1, 4:1 have been suggested. This is way too vague. I want to know which balun to use based on science, not guess-work. Or, dare I say this, should I simply forget about using a balun entirely? Just a direct coax feed? Or, still, feed the coax lead-in to a tuner?

3. What type of wire support is recommended? Pulleys? Counterweights? Scree-eyes? Polyester rope? Dacron rope?

4. Where is the best location for the attachment of the down-lead coax on the loop? Is the location performance-based? Mandatory? My desire would be to locate it on the leg nearest the house, so that the coax lead-in can be secured down the mast as it travels to the shack. But if that compromises performance, then I will take heed of what would be a better tapping point.

5. Lastly, would placing a robust surge arrestor (such as the Array Solutions/I.C.E. models or others) in the coax feed, mounted at ground-rod level, effect performance characteristics? or should I forgo this since it might alter the electrical balance of the loop's properties?

I know that this is quite a lot to ask. Further, I acknowledge that this topic has probably been covered a copious amount of times, so I apologize for you regulars in this group!

But I would be so appreciative for a DETAILED response. I may even be privately emailed if that would be in "better form."

Dean

Topic: 5137 Message: 5138

Dean,

As a non-expert, I can only offer brief comments.

1. Shape is not critical but best performance is when the largest area is encompassed by the loop.

2. No matter what balun you select, it will not have the proper ratio for all frequencies. Feeding a loop with window line or open wire line, with a tuner in the shack, gets around the ratio issue. That is why I dislike baluns when using my loops multiband.

3. Stainless steel hardware is the best to use, along with marine pulleys. I have pulleys in trees, as well as fiberglass poles attached to trees, with a pulley at the end of the pole.

4. For shortwave listening, I'd recommend attaching the feedline closest to the house, with weatherproof quick-disconnects for protection when storms approach.

5. Surge arrestors can help with static buildup, and nearby lightening strikes. I never use them (except the ones internal to my coax switches) and prefer to disconnect my feedlines from the house when storms approach.

73,

Evan, K9SQG

Dean , I transmit and receive on a 550ft delta loop. At my location the delta shape gives better matching that a sq. Ref the MMANA by m0mcx ,
https://www.youtube.com/watch?v=SOvhetU1_ps

I agree it is hard to find the best matched balun so I use a 4:1 and a 1:1 switchable balun for ladder line, Different band require different baluns.
http://i1102.photobucket.com/albums/g453/KD0ZZ/4to11to12.jpg
http://i1102.photobucket.com/albums/g453/KD0ZZ/4to11to11.jpg

I now run a 550ft delta trimmed, coax fed, with a 4:1 balun to a 1:1 match in the middle of the 40m phone band. Here is a chart from when it was a 80M size

http://i1102.photobucket.com/albums/g453/KD0ZZ/80MLoop_zpsa6e4cfe7.jpeg

I later expanded it to a 160m or 550ft loop. I dont plan on going any larger at this time unless you want to trim some more trees for me.
http://i1102.photobucket.com/albums/g453/KD0ZZ/160%20Loop/trees010_zpse5180867.jpg

I agree with Evan.

If you want the quietest receive antenna, that may be the one the furtherest from your house and any power lines.

I had a big loop, it was no quieter than my inverted V antennas. My quietest antenna was (and still is) a 35' vertical 175 ft away from the house. Everybody "knows" verticals are noisy on receive. But I can hear stations on that antenna that are "in the mud" on every other antenna I have (I have 5 operational antennas on 40 and 30m.)

If you want to know what balun to use, get an antenna analyzer (I use a Rig Expert AA-54) and see what the actual impedances are at the location you would put a balun. If you feed at a high impedance point and put a 4:1 balun at the other end of a quarter wave of ladder line, the impedance there will be low and a 4:1 will make it too low.

The ARRL handbook recommends NO balun, coax feed, in their section on loop antennas. That's probably a good idea, at least for receive antennas.

I had a 700' loop, later cut down to 600', later cut to 500', later cut to a 160m OCFD, and now currently a 200' center fed dipole. The big loop did nothing special for me.

The idea of no balun is NONSENSE.

Every feedline picks up common mode current, the closer to the house it comes, the more there is on it.
Common mode current increases the base noise level of the receiver.

You should always insert an RF choke (line isolator) where the feedline enters the house. You can (should) even do this for openwire.

BE SURE AND TWIST THE OPENWIRE FEEDLINE ABOUT ONE TURN PER YARD OF FEEDLINE. This goes a long way to reduce local generated common mode current.

I am putting together some information on how to build chokes for this on my web site. For transmitting, you must use high quality material (only Teflon insulated) due to the high voltage that may occur on some bands, but for receiving you may use wire or coax with standard insulation.

In fact you can simply wrap 13 to 15 turns of thin loud speaker twinline (similar to zip cord) around an FT-140-43 and it will do the trick. This has about 100 Ohms impedance and the short length required (abt. 18 inches) won’t have any noticeable impact on the antenna.

I will try to finish my web page by Monday.
See: http://www.dj0ip.de/open-wire-fed-ant/balanced-line-choke/

From: Andy
Topic: 5137 Message: 5142

Since it is a receive only antenna, I think that getting a match is unimportant. So a "ballpark" balun could be OK.

I don't follow the notion that feeding a loop with coax and no balun makes any sense. It unbalances the whole loop, which by itself was balanced, and this opens it up for receiving more noise and turning the coax itself into part of the antenna. For quietest operation, I think you need (at minimum a 1:1) balun if fed with coax.

Large horizontal loops are not omni-directional. There is some folklore and hand-waving about this that implies otherwise, but if you analyze them, you'll find they are not. The choice of feedpoint location determines which direction the main lobe goes.

The other thing the feedpoint location does, is change the impedance, so you can choose a corner or the middle of a side, to affect the SWR. But for a receive antenna, I don't think that matters much. At least not on HF (I'm not entirely positive about LF/MF, but I think those too).

Regards,
Andy

Fellow SkyWires Enthusiasts,

A tremendous amount of information about horizontal loops can be found at the W4RNL (sk) website as well as LB's work documented in the MFJ antenna books (volumes 1 and 2). He did a fair amount of computer analysis and showed plots of radiation patterns as a function of frequency and feedpoint. Also documented resistive and reactive components of the antennas based on frequency, height, etc.

Ran some tests a few years ago and compared my horizontal loop antenna (40 M about 12 ft off the ground fed with window line) with my 1/4 wave vertical mounted on the ground. As has been published, I found the loop to be between 1 and 2 S-units quieter than the vertical. This improved signal to noise ratio on receive.

73,

Evan, K9SQG

I would recommend using a 4:1 current balun, which will protect the receiver from static build up. To keep CMC down I would use a Common Mode choke, just after the 4:1 balun, which would keep the coax from picking up noise.

For shortwave listening, is a horizontal loop the best choice? Since as a general rule it had high angle of radiation, it will tend to pick up high angles. This isn’t always true as I have gotten some god DX on a loop on 80M (Shetlands, Antarctica, Falklands). But, to gain the selectivity (and take up a lot less room), you might want to consider a K9AY. You can select the direction, and it is easy to build.

For quietest operation, I think you need (at minimum a 1:1) balun if fed with coax.

Large horizontal loops are not omni-directional. There is some folklore and hand-waving about this that implies otherwise, but if you analyze them, you'll find they are not. The choice of feedpoint location determines which direction the main lobe goes.

The other thing the feedpoint location does, is change the impedance, so you can choose a corner or the middle of a side, to affect the SWR. But for a receive antenna, I don't think that matters much. At least not on HF (I'm not entirely positive about LF/MF, but I think those too).

Regards,

Andy

Subject: RE: [SkyWires] Horizontal Receiving Loop Questions From A Newbie

For shortwave listening, is a horizontal loop the best choice? Since as a general rule it had high angle of radiation, it will tend to pick up high angles. This isn’t always true as I have gotten some god DX on a loop on 80M (Shetlands, Antarctica, Falklands). But, to gain the selectivity (and take up a lot less room), you might want to consider a K9AY. You can select the direction, and it is easy to build.

Subject: Re: [SkyWires] Horizontal Receiving Loop Questions From A Newbie

I would recommend using a 4:1 current balun, which will protect the receiver from static build up. To keep CMC down I would use a Common Mode choke, just after the 4:1 balun, which would keep the coax from picking up noise.

Andy,

Sorry OM, you are a bit skewed from reality.

In all of the below, I'm referring to an 80m or 160m full size loop, not these tiny loops that can also be used for RX antennas. I am also referring to a relatively square loop.

"Where" you feed the loop does not change its impedance nor SWR.
The impedance is determined by length, height, and frequency, but not "where" it is fed.

A balun does help but at the feedpoint, it is probably better to use a 4:1 than a 1:1 if you are going to feed it with coax. An additional 1:1 should be inserted at the house to remove CMC.

The directivity of the loop is HIGHLY frequency dependent.
On it's fundamental it is 98% omni-directional.
On its second harmonic it is still rather Omni directional with some distortion.
On higher harmonics, it develops 4 distinct lobes, off of each of the 4 corners. Its signal strength difference between the 4 corners (at the other end of the QSO) is trivial from a standpoint of radiation pattern on the fundamental frequency.

On higher bands there is directivity off of all 4 corners and here you are correct, the strongest lobe is the one opposite the corner it is fed in, but there is no huge difference to the strength of the other 3 major lobes.
I'll pull a number out of the air and state it as 3 dB (max).

Evan,

As stated, your test comparison is meaningless.

Especially on 40m, when comparing antennas, if you don’t state time of day and distance of the QSO, it is meaningless. One antenna can be good for DX and bad for local work, or vice versa.

I’m sure you know what was going on but you didn’t give us enough information for it to be meaningful.

Check the same two antennas on transatlantic or transpacific QSOs and see if you still find the loop better.

Fellow SkyWires Enthusiasts,

A tremendous amount of information about horizontal loops can be found at the W4RNL (sk) website as well as LB's work documented in the MFJ antenna books (volumes 1 and 2). He did a fair amount of computer analysis and showed plots of radiation patterns as a function of frequency and feedpoint. Also documented resistive and reactive components of the antennas based on frequency, height, etc.

Ran some tests a few years ago and compared my horizontal loop antenna (40 M about 12 ft off the ground fed with window line) with my 1/4 wave vertical mounted on the ground. As has been published, I found the loop to be between 1 and 2 S-units quieter than the vertical. This improved signal to noise ratio on receive.

Rick,

The comparisons of my 40 M loop and 40 M vertical, for background and atmospheric noise, were made via A-B switching tests, with AVC on fast, and they were consistent.

In terms of propagation, I didn't mention those results. Based on something like 400 observations, for reports of my transmitted signal as well as received signal strength, I noticed that the loop antenna was better than the vertical close in and, as one goes further out they tend to converge in terms of performance. They were equal at about 1,000 miles out. Beyond that, the vertical was better than the loop.

I used what I thought was a reasonable procedure given my equipment and I tried to minimize sources of inaccuracies as best I could by doing A-B instantaneous switching. Given that the results were so consistent, I tend to believe them even though they are faulty. While all my results are faulty, some are useful to me.

GM Evan,

As I said, I believed that “you” know what happened, but your first description did not contain enough info for the rest of us. Now it’s much better.

In general, yes the vertical is noisier, but what matters overall is not the amount of noise but rather the signal to noise difference. When operating 40m or below, it is usually best to turn down the RF gain until the noise is almost gone, and then tune and listen to signals.

Of course for A/B testing there is a difference in RF gain setting. This complicates things.
So it’s best done on two good receivers.
After a couple of days, you swap the antenna between receivers and keep testing.
Normally it won’t make much difference which RX each antenna is on.

THEN you really see (rather “hear”) which one is better.

When I do my testing on 40m, I always record the date, time, station, and a/b reports.
What I found was much the same as what you found, except at dust (especially) and sometimes at twighlight (grey zone work), the condx are rapidly switching and then it was a wash.
Even the same signal would be stronger on one transmission with one antenna and on the next transmission on the other.

There is a second part of the results besides noise, but just as important. When working DX, although the noise may be higher with the vertical, the local QRM (stations out to 800 miles or so) are a couple S-Units weaker and this sometimes improves the signal-to-noise ratio, especially on a crowded band in a large contest.

I concluded, I needed both. Sometimes that additional S-Unit makes the difference between QSO and no QSO.

It’s easy to install a vertical, but we don’t always have room for the loop.
However if we have room for a loop, it doesn’t take much effort to put up a 40m vertical.

Good point Scott, “it has no discrimination.”
Well, that is 100% accurate for 80 and 40m, but changes on the higher bands.

When we call an antenna a cloud burner, we mean that a significant amount of the radiation is going straight up which is useless, except for NDSI. Unfortunately this is often misinterpreted to mean that it no good for DX on those bands. This is ludicrous. It is still a good antenna for DX, just not necessarily the best.

In 1979 I activated Andorra, as C31SE.
I was on top of the 2nd highest mountain in the country for about 7 days.
My only antenna was the horizontal loop, one wavelength long, fed with 600 Ohm openwire thru a home-brew link coupled tuner.

My log book is my favorite supporting argument for the claim above that this antenna is still good for DX.
Though only about 25 to 30 feet high, strung through the trees, I made hundreds of DX contacts on 80m.
Each morning I had long stateside pile-ups.
I did a short write up on that, here:
http://www.dj0ip.de/my-expeditions/andorra-1979/

If I could have only one antenna and had enough space, “this” would be it.

BUT DEFINITELY “NOT” MY FIRST CHOICE FOR A LOW BAND RECEIVING ANTENNA!

There are numerous antennas that will do a better job, when used with a good preamplifier.
The K9AY is one of them.

5153. Balanced Line Choke

Yahoo group: SkyWires
Date: 2016-01-31 15:25:21 UTC
From: rick@dj0ip.de
Topic: 5137 Message: 5153

I have added details of how to build an effective broadband RF choke (line isolator) for openwire.

Especially when using the loop as a receiving antenna, this kind of choke should be inserted at the shack end of the openwire.

http://www.dj0ip.de/open-wire-fed-ant/balanced-line-choke/

Note: this is NOT the balun I recommend using as the main “Tuner Balun”.

This one is used for cases one would insert a line isolator in a coaxial fed antenna.

Well, that is 100% accurate for 80 and 40m, but changes on the higher bands.

When we call an antenna a cloud burner, we mean that a significant amount of the radiation is going straight up which is useless, except for NDSI. Unfortunately this is often misinterpreted to mean that it no good for DX on those bands. This is ludicrous. It is still a good antenna for DX, just not necessarily the best.

In 1979 I activated Andorra, as C31SE.
I was on top of the 2nd highest mountain in the country for about 7 days.
My only antenna was the horizontal loop, one wavelength long, fed with 600 Ohm openwire thru a home-brew link coupled tuner.

My log book is my favorite supporting argument for the claim above that this antenna is still good for DX.
Though only about 25 to 30 feet high, strung through the trees, I made hundreds of DX contacts on 80m.
Each morning I had long stateside pile-ups.
I did a short write up on that, here:
http://www.dj0ip.de/my-expeditions/andorra-1979/

If I could have only one antenna and had enough space, “this” would be it.

BUT DEFINITELY “NOT” MY FIRST CHOICE FOR A LOW BAND RECEIVING ANTENNA!

There are numerous antennas that will do a better job, when used with a good preamplifier.
The K9AY is one of them.

Subject: RE: [SkyWires] Horizontal Receiving Loop Questions From A Newbie

Just to clarify, this was from the Midwest USA late in the evening in the winter. A loop does well as it is simple and inexpensive. At typical heights available – say 50 feet or

about 9 m, it is pretty much a cloud burner on 80M. On 40, there is some increase in low angle stuff, and I have worked a lot of DX on 40 ad 80M using a loop. However, it has no discrimination. That is why I like something like a K9AY for shortway listening….

Subject: RE: [SkyWires] Horizontal Receiving Loop Questions From A Newbie

For shortwave listening, is a horizontal loop the best choice? Since as a general rule it had high angle of radiation, it will tend to pick up high angles. This isn’t always true as I have gotten some god DX on a loop on 80M (Shetlands, Antarctica, Falklands). But, to gain the selectivity (and take up a lot less room), you might want to consider a K9AY. You can select the direction, and it is easy to build.

My $0.02…..

Subject: Re: [SkyWires] Horizontal Receiving Loop Questions From A Newbie

I would recommend using a 4:1 current balun, which will protect the receiver from static build up. To keep CMC down I would use a Common Mode choke, just after the 4:1 balun, which would keep the coax from picking up noise.

On Jan 30, 2016, at 11:04 AM, Andy ai.egrps@... <mailto:ai.egrps@...> [SkyWires] <SkyWires@yahoogroups.com <mailto:SkyWires@yahoogroups.com> > wrote:

Since it is a receive only antenna, I think that getting a match is unimportant. So a "ballpark" balun could be OK.

I don't follow the notion that feeding a loop with coax and no balun makes any sense. It unbalances the whole loop, which by itself was balanced, and this opens it up for receiving more noise and turning the coax itself into part of the antenna. For quietest operation, I think you need (at minimum a 1:1) balun if fed with coax.

Large horizontal loops are not omni-directional. There is some folklore and hand-waving about this that implies otherwise, but if you analyze them, you'll find they are not. The choice of feedpoint location determines which direction the main lobe goes.

The other thing the feedpoint location does, is change the impedance, so you can choose a corner or the middle of a side, to affect the SWR. But for a receive antenna, I don't think that matters much. At least not on HF (I'm not entirely positive about LF/MF, but I think those too).

Regards,
Andy

5155. 75 ohm coax for long run

Yahoo group: SkyWires
Date: 2016-02-14 16:44:36 UTC
From: w6mob@...
Topic: 5155 Message: 5155

All

I need just under 1/4 wavelength of 75ohm to match my loop to 50ohm
I was planning 1/4 wave of RG6 then 100feet of LMR400 to the shack.
The price of RG6 is $80 for 500 feet
Price of LMR400 equivalent for 500 feet about $500 both from HSC in Santa Clara.

Any reasons I should not run RG 6 all the way back to the shack. The loss 30MHz is vitually the same.

Thoughts?

Cheers

I ran RG6 from my fan dipoles to the shack, about 70 feet. Works well.
As long as you don't run more than 500 watts at low SWR you are good-to-go.
I did test a 70 foot of the RG6 with a watt meter at both ends compared to
a run of RG8
and the RG6 was as good as the RG8 at 10 meters. Also at 80 and 40 the loss
was low.
Here in Ecuador the RG6 is the only type available.
I buy the good type at $0.50 a meter, similar to the DirecTV type they use,
than the Chinese type that is $0.30 a meter.

Mick,

Not sure. Whatever frequency that "1/4 wavelength" refers to will not be 1/4 at frequencies/bands far from that frequency. So depending on the antenna and bands of interest, there could be matching issues. As to "loss at 30 mhz", I'm not an expert and not sure if there is a difference between the two coax types under matched versus mismatched conditions.

Let's see what the experts say. I'd like to learn...

All,

Thanks for the comments. Just to clarify as I forgot in the first message. This is to feed a 15meter single band loop and I only have 100Watts from my FT450D.

So I will try running 75ohm all the way and make sure it is (360*n + 90) degrees. According to SimSmith this would give me <= 1.2 SWR across the whole band.

Cheers

5160. 80m loop coax fed?

Yahoo group: SkyWires
Date: 2016-02-16 04:51:04 UTC
From: retrohertz@...
Topic: 5160 Message: 5160

Hi All,

I've just erected a full wave 80m loop horizontal, I'm wanting to use this for 80m and 40m only. I was going use ladder line as the feed, but given that the SWR is low on 80 and on the harmonic bands that I want to use (80/40) is there any advantage in using ladder line as feed line? Coaxial cable is clearly going to be easier to install (in my situation)

thanks for your help, hope that makes sense?

Hi Rhett

Easy answer

Lower loss when using it as a multiband antenna

imagine that rare dx station that can only be heard on 15m when you use the loop ... but not on the other antenna(s) ... (just an example)

the problem is that even if it is resonant on both bands ... it shows different impedance and so finding a balun to match it to you coax is the problem

maybe you can use a 1:2 and live with the slight mismatch on both bands

(on 80 a 1:1 and on 40 a 1:4 is needed)

.....

On the lowest band it will be low impedance (not the 100 ohms but a bit lower cause most hams have their loop low to ground) .. so then a 1:1 would fit best

On the harmonic bands it is higher (more in a few hundred ohms range)

... there you would need a 1:4 ...

So my guessing is that you MAYBE can use a 1:2

It also depends on your shack setup

Do you wanna use a tuner?? Or use tuner in the rig?? ... or no tuner at all??

Anyway ... a skyloop is my main antenna (168m) and you will love yours like I love mine :-)

Topic: 5160 Message: 5162

Hi All
I have a full wave 40 meter horizontal loop that I feed with coax, and constantly get great-amazing signal reports. I use the Alpha Delta “C” connector to hook up the coax. I also use an “ugly balun” just before the coax enters my house. I tried ladder line; but found that it picked up atmospheric noise, and signals were much lower.
That is my experience. If I had enough room I would really like to turn it into and 80 meter horizontal loop. (Horizontal loops are extremely quiet)

Topic: 5160 Message: 5163

I have two horizontal loops, one for 80, and one for 40, and I use both multiband depending on conditions. Have had good experience using 450 ohm window line but switched to 300 ohm transmitting window line due to lower visual cross section (aka, xyl pleaser). The 300 ohm has worked well also. Tuners have included MN-2000, MN-2700, MBVA, Millen 92200, and Palstart BT-1500A, and Johnson KW Matchbox, all of which have worked well on the various bands, except I don't operate 10 meters. Too, the window line is cheaper than coax and my weather proof disconnects are faster to connect and disconnect when storms are present.

Yes, it depends. My 40 m horizontal loop was 1-2 S-units lower in background noise than my 1/4 wave vertical in doing A-B tests at the same time. The loop enabled copying of weak signals I couldn't hear on the vertical. So yes, "Maybe, sometimes" and what works for one might not work for another. Let's keep sharing experiences and we all can learn...

Most of the baseband (broadband) antenna 'noise' depends on the specific location and environment that the antenna is located at.

A suburban residential neighborhood with microprocessors in the refrigerators, CFL's, high tension powerlines down the street provides more EM noise than if you were located on a rural location.

Case in point from last friday: my suburban residential location with high tension lines 80 feet away, had a power outage. With my battery powered SDR, the noise floor was a minimum 15 dB less than with the neighborhood powered up. Noise floor with no residential power was about -137 dBm, with power it rose to about -120 dBm. This was on 20 meters and a full wave delta loop 20 feet above the roofline.

You actually get some gain and low angle of radiation on this one. It seems it can be fed with coax as well.... I just don't have enough space to install a triangle 54 meters per side. Hmmm, maybe its time to start looking for another house.

I looked at the original set up of M0MCX and his megaloop. I put it up 80M size, It was great, trimmed a few trees*** and now have it 160M size, both coax fed with a home made 4:1 balun, adjusted to a low SWR in the middle of the 40M band. I work very little 160 so a high SWR on 160 is OK with me, my tuner in the radio takes care of that.

Hi Sigi,

Thanks heaps for your reply, I have stuck with 450 Ohm ladder line to a 4:1 balun with 6 foot of coax, Really happy with the performance on 80,40 and 30m. I'll try a 1:1 balun at sometime to compare the difference via the IC7600 and internal tuner.

So many variables due to height of the antenna, feedline location and multi bands. Much experimenting to be done.

5170. loop sky wire length vs swr vs loss?

Yahoo group: SkyWires
Date: 2016-03-09 18:37:11 UTC
From: denton sprague
Topic: 5160 Message: 5170

Have a 5 sided 470 ft loop up 30 ft fed with 600 ohm ladder line….works pretty well 160 thru 10 meters.
Am feeding it with about 45 ft of 600 ohm ladder line, to a 4 to 1 high power balun and then about 8 ft of rg-213 coax to shack tuner.
swr is pretty fair…worst is 10 to 1 at 1.8 mhz and radiation pattern according to EZNEC seems to be good.
Height is limited to 30 ft. cannot go higher with ordinances for multiple antenna masts.
I have room to expand loop to full sized 160 meter loop… 470 ft..but would I gain any real world advantage in terms of 160 meter performance, ground losses, swr etc.
EZNEC says no except for maybe a little better efficiency on lower part of 160 meters..and would loose a bit of local signals on 80 thru 40 meters.

5171. New Cutting Edge Antenna

The snowless winter has enabled us to do some advanced design work on our antennas these past few months.

These are looking good, but unfortunately won't be ready by Dayton.

See: http://www.dj0ip.de/cutting-edge-ant/

From: ke4nu7@...
Topic: 5172 Message: 5172

Hi, have a 520 ft loop up in a somewhat trapazoid configuration. I feed it with 450 LL into my MFJ tuner. It averages about 50 ft above ground strung between pine trees. Last night I work VK0EK on 40 cw on the first call. Today I worked FT4JA on 20 SSB first call again. This antenna really does well and I would recommend it as a cheap alternative to a tower and beams. My hf beam has been down for maintenance, I haven't had the decent wx to put it back up so I've had to rely on the loop and I couldn't be more pleased. 160 is the one band which is a cloud burner and I don't get any dx with but every other band it tunes up and plays well. Just my 2 cents worth for anyone who can put one up...DO IT ! 73 Alan

Alan,

As the models predict and our experiences show, as you move higher and higher in frequency above the fundamental frequency, you get more low angle lobes. For DX, the higher the better but it is amazing what a low, horizontal loop can do when propagation is good. With my 40 m horizontal loop 12 ft off the ground, on 40 I've worked consistently into Italy, Canary Islands, South Africa, etc. but the big benefit in my book is the reduced noise with the loop; it's all about signal to noise ratio, not raw signal strength. Enjoy your loop!

73,

Evan, K9SQG

5175. New Loop Entheusist - general questions

Yahoo group: SkyWires
Date: 2016-04-08 21:11:02 UTC
From: davekammler@...
Topic: 5175 Message: 5175

Hello,

I guess my biggest issue ... is the feedline .. coax or ladderline.

Second largest issue .. balun or no balun.

I've found the feed line discussion to be the largest point of contention during my

research.

I've read mixed review on whether or not this is a better local/region antenna vs. DX antenna. My strong preference is DX.

My antenna:
Total Length: 43.6m (144ft)(36ft per side)

-- at most I can probably do 300ft but very irregular looop shape maybe 6 or 7 unequal side lengths. Not sure what this will do to the radiation pattern.

Resonant on 40m. (80m would be desirable)

Feedline type: Coax 75ohm or ladderline 300ohm Other? (undetermined)
Feedline Length: 15m-22.7m (50-75ft) (approximate)
Coax feed cable type: (undetermined)

Coax feeder length of 7.7m(25.41ft).(approximate)

Power: Upto 600w

Above Ground Elevated: 7.57m- 9.09m(25 - 30ft)
Balun or no balun? Type?

What type of tuner? Other? I have LDG 200 PRO II and MFJ 949E.

Thanks

73, Dave
KG7WFZ

Not enough information to answer the question.
Please send more specifics.

How long and high is the loop?
What bands do you wish to use it on.

The main reason you hear different opinions of anything is because different people have different wants and needs and expectation levels. Most of the time you are getting apples to oranges answers without knowing it.

Ask 6 hams and you will get a dozen answers.
I feed mine with coax and a home made 4:1 Guanella balun.
Delta shape and adjusted to a low SWR in the middle of the 40M band
Used mainly on 40m , I work mostly DX, can work 160 thru 6 but balun is adjusted for lower bands.
Your LDG would be nice but it is not for 600W
Check out delta loop info by m0mcx at
https://www.youtube.com/watch?v=SOvhetU1_ps

Dave

A loop 25 to 30 ft. high, “square”, and a full wavelength on 80m behaves quite differently on different bands.

• On 80m it is called a cloud burner but this is nonsense. It has a vertical radiation similar to a magnetic loop, in that it radiates more or less in all take-off angles. Its horizontal pattern is omni-directional. DX-wise, it will be slightly weaker than the broadside of a dipole at ½ wavelength height (67 ft.), but certainly just as good as one at 30 ft. height. Off the ends of the dipole it will be significantly better. AND, because it is “also” a cloud burner, it will be better than the dipole for NDIS.

• On 40m it ceases to be a cloud burner but still has a large vertical take-off angle covering from relatively low to moderately high take-off angles. This makes it good for DX and NVIS. Its horizontal pattern begins to resemble a 4-leaf clover with major lobes off of all 4 corners, yet due to its low proximity to earth, it fills in the area between the lobes and still radiates a fairly decent signal – though a couple of S-units down from the major lobes - off of its sides. In my opinion, a 2 wavelength loop antenna for the low bands is the very best “reasonable” wire antenna one can possibly have.

• On 20m it starts to get real interesting for DX. Here the lobes are (horizontally) again much more focused on the 4 corners, with the vertical take-off angle again ranging from low to medium. This makes it outstanding for DX. My experience has been that an 80m horizontal loop has just as strong of a DX signal in the direction of all 4 corners as a 3 element beam or 2 element quad at the same height – and there is no rotor needed.

• 15m is very similar to 20.

• I can’t recall exactly how it was on 10m but it was still very good at DX. In any case it had a very flat take-off angle.

People who call this antenna a cloud burner are those who I call “Text Book Turkeys”.
They live in a world of mental masturbation built on over-rated technology.
They should get off of their lazy arse and simple build one of these and try it.
Then they would change their opinion of this great antenna.

I didn’t build one of these.
I’ve built about 20 of them.
I know.

The icing on the cake is the quietness of the antenna.

And the cherry on the icing is when you open the far end, feed it with a backwards 4:1 balun (i.e. 1:4 balun) and run it effectively on 160m. It’s not a “killer” on that band but it does work quite well.

Dave,

If it is a mono band situation, then coax might work ok; 1:1 or 2:1 balun at the antenna would be ok. Multi band suggests ladder line or window line, with a balun in the shack or a balanced tuner.

These are very coarse notions, installation specifics could alter them.

I also agree with Everett. My delta loop is a 160 size, fed with RG-8U, and a home made duel rod balun. Balun sketch
http://i1102.photobucket.com/albums/g453/KD0ZZ/2rod.jpg
The same sketch can be used for duel torrid, the rods gave better readings when testing the balun into a dummy load. I tried duel winding's on a single core, duel core and duel rod. Dummy load is a 200 ohm carbon resistor set up.
http://i1102.photobucket.com/albums/g453/KD0ZZ/Balunjpeg_zps41dd0ff6.jpg
I got into my making my own due to high SWR readings into a dummy load with "store" bought baluns.

Subject: Re: [SkyWires] New Loop Entheusist - general questions

Dave,

If it is a mono band situation, then coax might work ok; 1:1 or 2:1 balun at the antenna would be ok. Multi band suggests ladder line or window line, with a balun in the shack or a balanced tuner.

These are very coarse notions, installation specifics could alter them.

Subject: [SkyWires] New Loop Entheusist - general questions

Hello,

I guess my biggest issue ... is the feedline .. coax or ladderline.

Second largest issue .. balun or no balun.

I've found the feed line discussion to be the largest point of contention during my

research.

I've read mixed review on whether or not this is a better local/region antenna vs. DX antenna. My strong preference is DX.

My antenna:

Total Length: 43.6m (144ft)(36ft per side)

-- at most I can probably do 300ft but very irregular looop shape maybe 6 or 7 unequal side lengths. N ot sure what this will do to the radiation pattern.

Resonant on 40m. (80m would be desirable)

Feedline type: Coax 75ohm or ladderline 300ohm Other? (undetermined)

Feedline Length: 15m-22.7m (50-75ft) (approximate)

Coax feed cable type: (undetermined)

Coax feeder length of 7.7m(25.41ft). (approximate)

Power: Upto 600w

Above Ground Elevated: 7.57m- 9.09m(25 - 30ft)

Balun or no balun? Type?

What type of tuner? Other? I have LDG 200 PRO II and MFJ 949E.

Thanks

73, Dave

Rick,

Well, it depends, hi hi. My comments were based upon my experiments and findings that work for "most cases", at least my installations with varying lengths of the loops, heights, feed line lengths, etc. etc. Yes, sometimes one can hit it lucky with various combinations (antenna lengths, heights, and feed line type/length) and then it works for the respective user. But deviations within those parameters might negate the results for others. And some antennas are more sensitive to site specifics than others. Hence, I just provided some overall, "brute force" thoughts that seem to work in most cases. Thanks for that reference/link you sent.

73,

Evan

5185. RE: [SkyWires] New Loop Entheusist - general questions

Yahoo group: SkyWires
Date: 2016-04-09 14:02:15 UTC
From: rick@dj0ip.de
Topic: 5175 Message: 5185

I think the fact that the two toroids balun had higher SWR was just bad luck.
The cores were probably much different in permeability.
With my dual toroid baluns I get under 1.1:1 from 3.5 to about 22 MHz, then it slowly rises to just under 1.2:1.

In the several hundred toroids I have wrapped 99% were within 17% of each other, but 3 or 4 were way out in right field and could not be used for that purpose; so I just used them for single core chokes.

The problem is the poor permeability tolerances in toroids or ferrite sticks.
According to W8JI they can easily vary as much as 20%.
This means, with the same number of turns, you have a much different impedance between the two coils which throws the balance off. The SWR rises.

I usually wrap my toroids 100 at a time, measure them all, then put them into matched pairs with less than 1% variance. In fact most are less than 1/2 % variance. This enables me to get such a good SWR curve across the hf spectrum.

Obviously this is not something people will want to do.
And for those of you who doubt I do this, sorry Charlie - I’ve done it many times.
See: http://www.aerial-51.com/quality/ (middle of the page)

There is no electrical advantage of using a toroid instead of a stick or vice versa.
But there is a mechanical advantage using toroids.
Most of the magnetic flux remains inside the donut, so mounting the balun near metal objects does not have much negative influence; it does when using sticks instead of toroids.

Winding both transmission lines on a single stick or toroid is a bad idea.
Your CMI goes to hell in a hand basket when you do that.

I also agree with Everett. My delta loop is a 160 size, fed with RG-8U, and a home made duel rod balun. Balun sketch
http://i1102.photobucket.com/albums/g453/KD0ZZ/2rod.jpg
The same sketch can be used for duel torrid, the rods gave better readings when testing the balun into a dummy load. I tried duel winding's on a single core, duel core and duel rod. Dummy load is a 200 ohm carbon resistor set up.
http://i1102.photobucket.com/albums/g453/KD0ZZ/Balunjpeg_zps41dd0ff6.jpg
I got into my making my own due to high SWR readings into a dummy load with "store" bought

baluns.

You are totally correct Evan, they do certainly vary from one place to another.
The 2:1 will most likely have a better match on 80m but on the higher bands, the 4:1 will probably be better.

At the end of the day, we must simply try it.
It’s very easy to match 2:1 on a single band, but a 2:1 balun is a bit more difficult.
A 4:1 balun is simple to build.

Dave,

I will put my 3 cents worth below…

73 - Rick, DJ0IP
(Nr. Frankfurt, Germany)

Subject: [SkyWires] New Loop Entheusist - general questions

I guess my biggest issue ... is the feedline .. coax or ladderline.

>> Ladderline will have lower loss, but if we're talking 50 – 75 ft., there will be no noticeable difference (at the other end of the QSO) on the bands where you have an SWR of 4:1 or better AT THE FEEDPOINT. With coax you MUST use a balun; with ladderline you don't need a balun at that point.

Second largest issue .. balun or no balun.

>> Wrong Question. Should read 1, 2, or 3 Baluns?

>> At the feedpoint, you need a balun when using coax. Depending on which bands are more important, a 2:1 balun might be better or a 4:1 might be better. "Location" will also affect this choice. At the end of the day you'll probably have to try both. Once the coax gets to the house, you should always place a 1:1 current choke (which is also a balun) at the house. This can be either a Guanella or a good Maxwell.

>> If ladder line, then no balun is required at the feedpoint, but at the matchbox, do not use the internal balun of the matchbox (if they have one at all). Use an external balun. WE SHOULD ALWAYS USE A 1:1 CURRENT BALUN AS A TUNER BALUN - ALWAYS!!! (NO EXCEPTIONS). In addition, we sometime need to insert a 4:1 balun between the tuner balun and the feedline. This may be either a Ruthroff (voltage) or Guanella (current) balun.

>> If anyone tells you different, then have that person read this page and study the info on the links at the bottom of the page:
http://www.dj0ip.de/balun-stuff/tuner-baluns/

I've found the feed line discussion to be the largest point of contention during my research.

>> with good reason. How well the loop will radiate power depends on how you match and feed it.

I've read mixed review on whether or not this is a better local/region antenna vs. DX antenna. My strong preference is DX.

>> I already wrote a whole nickle's worth on this one in an earlier post.

My antenna:
Total Length: 43.6m (144ft)(36ft per side)

-- at most I can probably do 300ft but very irregular loop shape maybe 6 or 7 unequal side lengths. Not sure what this will do to the radiation pattern.

>> The radiation pattern should not be toooo distorted by this. After all it is the current peaks and nodes that determining where RF is radiated, not the shape itself. Identify the 90 degree (electrical) points; specifically feedpoint, and the 1/4, 1/2, 3/4 of the way around the loop.
Then go back and read my earlier post on the radiation pattern of a square (or diamond) loop. Assume each of these points represents one of the corners. Then you'll have a close idea of how it will radiate, by band.

Resonant on 40m. (80m would be desirable)

>> 80m: Piece of Cake. If you open the loop at the 1/2 mark (opposite the feedpoint) and then feed it with a 4:1 Guanella balun - INSERTED UPSIDE DOWN - And then with 50 or 75 Ohm coax to the shack, it will work pretty good on 80m.

>> Opening and closing the loop is also easy. Simply insert an insulator at the halfway point, and solder a quarter wavelength of coax across the insulator; then short the far end of the coax. This stub creates an automatic switch, open on 80m and closed on all other bands.

>> If you use a home-brew 4:1 Guanella balun, it is very easy to switch it to 3 different configurations: 4:1 / 1:1 / 1:4 . You probably won't need the 1:4. A pair of DPDT relays is all that is required to switch back and forth between 4:1 and 1:4. You can even run the switching voltage through the coax.

>> If you use ladderline, again no problem working 80m, as long as you have inserted the auto switch at the halfway mark of the loop. The impedance at the feedpoint is 12.5 Ohms - or close, depending on local surroundings. Run the 300 Ohms to the shack, then through the 1:1 Current Balun, and into the tuner. There will be transmission line transformation on the feedline, so I can't predict what the impedance in the shack will be on 80; you may need to play with feedline length to bring it within the range of your matchbox.

Feedline type: Coax 75ohm or ladderline 300ohm Other? (undetermined)

>> Well personally I prefer ladderline but then it is best to have a real symmetrical matchbox, which neither of your two boxes are. Clearly coax is more convenient.

Feedline Length: 15m-22.7m (50-75ft) (approximate)
Coax feed cable type: (undetermined)
Coax feeder length of 7.7m(25.41ft).(approximate)

Power: Upto 600w
>> Neither of your two matchboxes will handle this power.

Above Ground Elevated: 7.57m- 9.09m(25 - 30ft)

Balun or no balun? Type?
>> addressed above

What type of tuner? Other? I have LDG 200 PRO II and MFJ 949E.
>> This depends first on what feedline you choose. If you use coax, these two will work. If

you choose openwire, I would look to finding an old Johnson Viking Matchbox, but BE SURE to check inside if the coils are still OK. Often they have melted and are nowhere close to being symmetrical. Otherwise new purchase is quite limited to the MFJ-974 (200w) and for high power, the MFJ-976 or Palstar BT-1500. Here the Palstar would be preferable but it costs more.
There are even better tuners than these but the prices shoot up over $1000.

Thanks
>> You're welcome. 73s and gud luk with the ANT; Rick, DJ0IP

For clarity, the automatic switch to open and close the loop is a quarter wavelength of coax “on 80 meters.”

You must take its velocity factor into consideration when calculating the length.

So we’re talking about something in the range of 43’ of coax here.

>> If anyone tells you different, then have that person read this page and study the info on the links at the bottom of the page:
http://www.dj0ip.de/balun-stuff/tuner-baluns/

I've found the feed line discussion to be the largest point of contention during my research.

>> with good reason. How well the loop will radiate power depends on how you match and feed it.

I've read mixed review on whether or not this is a better local/region antenna vs. DX antenna. My strong preference is DX.

>> I already wrote a whole nickle's worth on this one in an earlier post.

My antenna:
Total Length: 43.6m (144ft)(36ft per side)
-- at most I can probably do 300ft but very irregular loop shape maybe 6 or 7 unequal side lengths. Not sure what this will do to the radiation pattern.

>> The radiation pattern should not be toooo distorted by this. After all it is the current peaks and nodes that determining where RF is radiated, not the shape itself. Identify the 90 degree (electrical) points; specifically feedpoint, and the 1/4, 1/2, 3/4 of the way around the loop.
Then go back and read my earlier post on the radiation pattern of a square (or diamond) loop. Assume each of these points represents one of the corners. Then you'll have a close idea of how it will radiate, by band.

Resonant on 40m. (80m would be desirable)

>> 80m: Piece of Cake. If you open the loop at the 1/2 mark (opposite the feedpoint) and then feed it with a 4:1 Guanella balun - INSERTED UPSIDE DOWN - And then with 50 or 75 Ohm coax to the shack, it will work pretty good on 80m.

>> Opening and closing the loop is also easy. Simply insert an insulator at the halfway point, and solder a quarter wavelength of coax across the insulator; then short the far end of the coax. This stub creates an automatic switch, open on 80m and closed on all other bands.

>> If you use a home-brew 4:1 Guanella balun, it is very easy to switch it to 3 different configurations: 4:1 / 1:1 / 1:4 . You probably won't need the 1:4. A pair of DPDT relays is all that is required to switch back and forth between 4:1 and 1:4. You can even run the switching voltage through the coax.

>> If you use ladderline, again no problem working 80m, as long as you have inserted the auto switch at the halfway mark of the loop. The impedance at the feedpoint is 12.5 Ohms - or close, depending on local surroundings. Run the 300 Ohms to the shack, then through the 1:1 Current Balun, and into the tuner. There will be transmission line transformation on the feedline, so I can't predict what the impedance in the shack will be on 80; you may need to play with feedline length to bring it within the range of your matchbox.

Feedline type: Coax 75ohm or ladderline 300ohm Other? (undetermined)

>> Well personally I prefer ladderline but then it is best to have a real symmetrical matchbox, which neither of your two boxes are. Clearly coax is more convenient.

Feedline Length: 15m-22.7m (50-75ft) (approximate)
Coax feed cable type: (undetermined)
Coax feeder length of 7.7m(25.41ft).(approximate)

Power: Upto 600w
>> Neither of your two matchboxes will handle this power.

Above Ground Elevated: 7.57m- 9.09m(25 - 30ft)

Balun or no balun? Type?
>> addressed above

What type of tuner? Other? I have LDG 200 PRO II and MFJ 949E.
>> This depends first on what feedline you choose. If you use coax, these two will work. If you choose openwire, I would look to finding an old Johnson Viking Matchbox, but BE SURE to check inside if the coils are still OK. Often they have melted and are nowhere close to being symmetrical. Otherwise new purchase is quite limited to the MFJ-974 (200w) and for high power, the MFJ-976 or Palstar BT-1500. Here the Palstar would be preferable but it costs more.
There are even better tuners than these but the prices shoot up over $1000.

Thanks

5189. RE: [SkyWires] New Loop Entheusist - general questions

Yahoo group: SkyWires
Date: 2016-04-10 10:51:10 UTC
From: rick@dj0ip.de
Topic: 5175 Message: 5189

Sorry guys, I need to start proof reading better before hitting send.

Mistake in this paragraph:
>> If you use a home-brew 4:1 Guanella balun, it is very easy to switch it to 3 different configurations: 4:1 / 1:1 / 1:4 . You probably won't need the 1:4. A pair of DPDT relays is all that is required to switch back and forth between 4:1 and 1:4. You can even run the switching voltage through the coax.

It should read:
>> If you use a home-brew 4:1 Guanella balun, it is very easy to switch it to 3 different configurations: 4:1 / 1:1 / 1:4 . You probably won't need the ***1:1.*** A pair of DPDT relays is all that is required to switch back and forth between 4:1 and 1:4. You can even run the switching voltage through the coax.

Subject: RE: [SkyWires] New Loop Entheusist - general questions

Dave,

I will put my 3 cents worth below…

73 - Rick, DJ0IP
(Nr. Frankfurt, Germany)

Subject: [SkyWires] New Loop Entheusist - general questions

I guess my biggest issue ... is the feedline .. coax or ladderline.

>> Ladderline will have lower loss, but if we’re talking 50 – 75 ft., there will be no noticeable difference (at the other end of the QSO) on the bands where you have an SWR of 4:1 or better AT THE FEEDPOINT. With coax you MUST use a balun; with ladderline you don’t need a balun at that point.

Second largest issue .. balun or no balun.

>> Wrong Question. Should read 1, 2, or 3 Baluns?

>> At the feedpoint, you need a balun when using coax. Depending on which bands are more important, a 2:1 balun might be better or a 4:1 might be better. "Location" will also affect this choice. At the end of the day you'll probably have to try both. Once the coax gets to the house, you should always place a 1:1 current choke (which is also a balun) at the house. This can be either a Guanella or a good Maxwell.

>> If ladder line, then no balun is required at the feedpoint, but at the matchbox, do not use the internal balun of the matchbox (if they have one at all). Use an external balun. WE SHOULD ALWAYS USE A 1:1 CURRENT BALUN AS A TUNER BALUN - ALWAYS!!! (NO EXCEPTIONS). In addition, we sometime need to insert a 4:1 balun between the tuner balun and the feedline. This may be either a Ruthroff (voltage) or Guanella (current) balun.

>> If anyone tells you different, then have that person read this page and study the info on the links at the bottom of the page:
http://www.dj0ip.de/balun-stuff/tuner-baluns/

I've found the feed line discussion to be the largest point of contention during my research.

>> with good reason. How well the loop will radiate power depends on how you match and feed it.

Rick,

I concur. And there is a lot to be learned by experimenting thus comparing theory/modeling with application. The models don't do a great job regarding site specifics.

As they say, all models are wrong, but some models are useful. AND the best antenna on paper doesn't yield as many QSOs as an antenna that is actually installed.

You are totally correct Evan, they do certainly vary from one place to another.
The 2:1 will most likely have a better match on 80m but on the higher bands, the 4:1 will probably be better.

At the end of the day, we must simply try it.
It’s very easy to match 2:1 on a single band, but a 2:1 balun is a bit more difficult.
A 4:1 balun is simple to build.

Subject: Re: [SkyWires] New Loop Entheusist - general questions

Rick,

Well, it depends, hi hi. My comments were based upon my experiments and findings that work for "most cases", at least my installations with varying lengths of the loops, heights, feed line lengths, etc. etc. Yes, sometimes one can hit it lucky with various combinations (antenna lengths, heights, and feed line type/length) and then it works for the respective user. But deviations within those parameters might negate the results for others. And some antennas are more sensitive to site specifics than others. Hence, I just provided some overall, "brute force" thoughts that seem to work in most cases. Thanks for that reference/link you sent.

73,

Evan

Subject: Re: [SkyWires] New Loop Entheusist - general questions

Dave,

If it is a mono band situation, then coax might work ok; 1:1 or 2:1 balun at the antenna would be ok. Multi band suggests ladder line or window line, with a balun in the shack or a balanced tuner.

These are very coarse notions, installation specifics could alter them.

GM Evan,

I like to hassle the people who do nothing but model ‘til the cows come home.
“ Did you work any DX today on that model ? ” (hi)

But let me be perfectly clear: I am the sales and service manager for Spiderbeam Antennas.
There would not even be a Spiderbeam Yagi if we had not had modeling software.

Next month in QST you will see a review of an antenna I designed. (page 6 and 7).
That antenna likely would not have been possible if we had not modeled it first.

But don’t think the models were spot on.
It took LOTS of hours of field testing and pruning before the antennas actually worked on all bands as they should. And the model didn't do a darn thing to help design the balun. That bit took one year and over 500 hours of field work testing different balun technologies and their ability to cope with the heavy CMC produced by OCFD antennas.

With multi-band antennas, it’s always a 2-sided sword.
You fix one band and throw another out.

The Rubber Hits The Road On-The-Air (NOT on the keyboard)!

5193. RE: [SkyWires] New Loop Entheusist - general questions

Yahoo group: SkyWires
Date: 2016-04-11 12:52:13 UTC
From: rick@dj0ip.de
Topic: 5175 Message: 5193

We moved it from pages 6 and 7 to pages 52 & 53, just to confuse the Russians.

We’re back doing that again.

Ok Rick,

Your review must be in the witness protection program: I can't find it in pages 6-7 of the May QST which arrived today in digital form.

More specifically, where did/ will it appear?

GM Evan,

I like to hassle the people who do nothing but model ‘til the cows come home.
“ Did you work any DX today on that model ? ” (hi)

But let me be perfectly clear: I am the sales and service manager for Spiderbeam Antennas. There would not even be a Spiderbeam Yagi if we had not had modeling software.

Next month in QST you will see a review of an antenna I designed. (page 6 and 7).
That antenna likely would not have been possible if we had not modeled it first.

But don’t think the models were spot on.
It took LOTS of hours of field testing and pruning before the antennas actually worked on all bands as they should. And the model didn't do a darn thing to help design the balun. That bit took one year and over 500 hours of field work testing different balun technologies and their ability to cope with the heavy CMC produced by OCFD antennas.

With multi-band antennas, it’s always a 2-sided sword.
You fix one band and throw another out.

You are totally correct Evan, they do certainly vary from one place to another.
The 2:1 will most likely have a better match on 80m but on the higher bands, the 4:1 will probably be better.

At the end of the day, we must simply try it.
It’s very easy to match 2:1 on a single band, but a 2:1 balun is a bit more difficult.
A 4:1 balun is simple to build.

Rick,

Well, it depends, hi hi. My comments were based upon my experiments and findings that work for "most cases", at least my installations with varying lengths of the loops, heights, feed line lengths, etc. etc. Yes, sometimes one can hit it lucky with various combinations (antenna lengths, heights, and feed line type/length) and then it works for the respective user. But deviations within those parameters might negate the results for others. And some antennas are more sensitive to site specifics than others. Hence, I just provided some

overall, "brute force" thoughts that seem to work in most cases. Thanks for that reference/link you sent.

73,

Evan

Subject: Re: [SkyWires] New Loop Entheusist - general questions

Dave,

If it is a mono band situation, then coax might work ok; 1:1 or 2:1 balun at the antenna would be ok. Multi band suggests ladder line or window line, with a balun in the shack or a balanced tuner.

These are very coarse notions, installation specifics could alter them.

Hello,

I guess my biggest issue ... is the feedline .. coax or ladderline.

Second largest issue .. balun or no balun.

I've found the feed line discussion to be the largest point of contention during my research.

I've read mixed review on whether or not this is a better local/region antenna vs. DX antenna. My strong preference is DX.

My antenna:
Total Length: 43.6m (144ft)(36ft per side)
-- at most I can probably do 300ft but very irregular looop shape maybe 6 or 7 unequal side lengths. N ot sure what this will do to the radiation pattern.

Resonant on 40m. (80m would be desirable)
Feedline type: Coax 75ohm or ladderline 300ohm Other? (undetermined)
Feedline Length: 15m-22.7m (50-75ft) (approximate)
Coax feed cable type: (undetermined)
Coax feeder length of 7.7m(25.41ft).(approximate)
Power: Upto 600w
Above Ground Elevated: 7.57m- 9.09m(25 - 30ft)
Balun or no balun? Type?
What type of tuner? Other? I have LDG 200 PRO II and MFJ 949E.

Thanks

5196. Revisiting the horizontal loop and looking for some solid design criteria

Yahoo group: SkyWires
Date: 2016-05-26 15:21:49 UTC
From: kl7rs@...
Topic: 5196 Message: 5196

I want to build a multi-band 80-6m SkyWire horizontal loop for field day.

Like so many others who have posted here, I have been all over the internet and now feel overwhelmed with all of the contradictions and misleading information out there regarding the design of these loops.

I have seen loop lengths anywhere from 270 - 300 feet, lots of different types and ratios of baluns, coax vs windowed ladder line, and some folks say the length of the ladder line makes no difference yet others say it does because it is in fact a matching transformer (I use a ZS6BKW and tend to believe this wholeheartedly).

So I was hoping to get a few folks to post the SPECIFICS of their working antennas, in an effort to at least get an effecient design that is proven to work as many bands as possible between 80-6 meters.

I'd like to know the following:

Length of wire
height

shape of loop
feed point (corner, edge, etc)
type of feed line (ladder line type, coax type)
how is the feed line connected to the wire (balun / direct connect, etc)
length of the feed line (this appears to be critical)
if you use a balun, choke or both, where are they positioned along the feedline
maybe a list of the bands used and swr readings (without a tuner)

if you use a tuner what is it and where is it placed (at the antenna, shack etc.)
if you use a tuner, are there any bands it has trouble with

From what reading I've done, it appears it is almost impossible to get the loop to be resonant on all of the bands used and many people still use a tuner at the shack to fine tune the antenna. If this is the case, then that's perfectly fine. If I'm wrong in this assumption, please correct me.

My initial design was going to be to use 282 feet of number 14 wire, use a 4:1 current balun at the antenna and then 75 feet of coax back to the station. If a tuner is required, I do have a 300w MFJ auto-tuner that usually does pretty good. After a bunch of reading, I'm confused and would like to know exactly what is working for other folks.

Here is a chart from my 80m delta loop, good for all bands but 17 and that is not used for field day
http://i1102.photobucket.com/albums/g453/KD0ZZ/80MLoop_zpsa6e4cfe7.jpeg
Here is the layout for my loop, I did make a fine adjustment for best SWR in the middle of the 40M phone band,
http://i1102.photobucket.com/albums/g453/KD0ZZ/80MDelta.jpg
My loop will work on 6M but the 4:1 current balun is not optimized for 6M, it is also adjusted for the lower bands with a center frequency of 10 Mhz

Rich, Kd0zz

Like so many others who have posted here, I have been all over the internet and now feel overwhelmed with all of the contradictions and misleading information out there regarding the design of these loops.

I have seen loop lengths anywhere from 270 - 300 feet, lots of different types and ratios of baluns, coax vs windowed ladder line, and some folks say the length of the ladder line makes no difference yet others say it does because it is in fact a matching transformer (I use a ZS6BKW and tend to believe this wholeheartedly).

So I was hoping to get a few folks to post the SPECIFICS of their working antennas, in an effort to at least get an effecient design that is proven to work as many bands as possible between 80-6 meters.

I'd like to know the following:

Length of wire

height

shape of loop

feed point (corner, edge, etc)

type of feed line (ladder line type, coax type)

how is the feed line connected to the wire (balun / direct connect, etc)

length of the feed line (this appears to be critical)

if you use a balun, choke or both, where are they positioned along the feedline

maybe a list of the bands used and swr readings (without a tuner)

if you use a tuner what is it and where is it placed (at the antenna, shack etc.)

if you use a tuner, are there any bands it has trouble with

From what reading I've done, it appears it is almost impossible to get the loop to be resonant on all of the bands used and many people still use a tuner at the shack to fine tune the antenna. If this is the case, then that's perfectly fine. If I'm wrong in this assumption, please correct me.

My initial design was going to be to use 282 feet of number 14 wire, use a 4:1 current balun at the antenna and then 75 feet of coax back to the station. If a tuner is required, I do have a 300w MFJ auto-tuner that usually does pretty good. After a bunch of reading, I'm confused and would like to know exactly what is working for other folks.

Thanks Rich. Your 283 feet falls more inline with the 282 feet that I came up with. What I don't understand is how some folks are using 270-275 feet and still getting them to work multiple bands.

Can you tell me if there is much difference in making the loop a square vs a triangle? I've read where the more area inside the loop, the better the performance.

Norm

"What I don't understand is how some folks are using 270-275 feet and still getting them to work multiple bands."

Height, wire size, wire insulated or not, type of ground below it. THESE all make a difference in the required length.

If running openwire, length is almost unimportant.
Length of feedline changes the impedance in the shack but with a good enough matchbox, that won't make much difference.

If feeding with coax, then length of antenna, and balun type make a very critical difference.
See: http://www.dj0ip.de/loop-antennas/8-band-horizontal-loop/
For one example on how to do it.

Sorry for the mixed up email. Had a storm come thru and lost all, my ISP is thru a satellite like direct tv uses. Bad weather and all is gone.
Check out "mega loop antenna" MMANA info on building a delta loop.
https://www.youtube.com/watch?v=SOvhetU1_ps
Size & shape does matter, I tried a almost square and it was no good, delta loop with 60 degree corners works fine. I cant give you any reading today because it worked so well I changed it to a 160M size. Had to remove a few trees to get it done.
I first put up the 283, 12ga, size then adjusted the loop to a low SWR in the middle of the 40m phone band, (a few feet shorter) I have a full size 40M vertical with a 8 ft high feed point w/sloping radials and the loop always out performs the vertical
Feed point for the delta loop is about 40ft as are the other two points , wire does droop to about 30 between because the tree tops are not too strong.

Hi Norm,

Start long and trim to get it where you want it. To get the best results on the higher bands you will need to be at the low end of 80 meters. I experimented with 2.25:1 and 4:1 baluns, the 4:1 balun is the best.

I have a couple articles in the files section of this site that may be of some value to you with several sweep showing the SWR from 80 through 10, it works on all bands in between with the exception of 60 meters. For my installation I found 275' to be the ideal length using a 4:1 cut tent balun.

Rich,

You must be the first person on the planet to claim the square loop does not work.
It has always worked great for me and I have used it often as full size 80m and 40m versions.

When you say the large loop always works better than the vertical on 40m, that is a very powerful statement.
Obviously for contacts out to about 1000 miles it will blow the vertical away.
How about when working long haul DX, such as Europe or Pacific?

Rick I should have said the the "rectangular" shaped loop worked with ladder line but not as well coax fed, the delta loop , 80M size worked good on 40M with a 4:1 balun and coax fed.
The original question was about a antenna for field day use not DX so I would pick the loop for field day. Sorry about the mix up.

Typically the horizontal loop is somewhat insensitive to shape based upon my experiments over the past 25 years. I currently have two horizontal loops, one for 40 meters and one for 80 meters and am quite pleased with them.

As Rick has mentioned, performance is a function of distance, so to speak. Several years ago I did some observational tests comparing my 40 M 1/4 wave vertical against my 40 M horizontal loop. Close in, the loop was stronger than the vertical by as much as 20-25 db. As the distance between stations increased to about 1,000 miles, the antennas were equal; beyond that the vertical was stronger than the horizontal loop. This was based upon over 400 observations, receiving and/or transmitting, with A-B switching between antennas.

Too, during the testing, I noticed that the loop was 1-2 S-units lower with regard to background noise.

My loops are very broad in terms of the SWR curve and, by experimenting, I've found that a resonant versus non-resonant loop seems to have minimal to no effect on transmit or receive signal strengths. I don't pretend to understand all the theory, I'm just very pleased with the horizontal loop antennas. And to me, perfect is the enemy of good enough.

73,

Evan, K9SQG

OK, now we FULLY agree.

The loop is fantastic for Field Day.

I used it for many years, until they changed our rules allowing us only one single support mast.

That was the end of the loop’s domination in FD here.

I'm pretty much going to be limited to a standard 80m loop this year, so I won't be putting up a mega-loop.

What I'm hearing is that a 80-6m loop isn't an easily duplicated antenna. Dimensions can vary widely based upon where it is being installed. There doesn't seem to be a widely accepted method of feeding the antenna where specific lengths of coax seem to work well.

I can't even find a widely accepted feed method where the length of the window line is shown to work in most circumstances. I know window line acts as a transformer and it can be pretty hard finding a specific length can be used with a tuner on multiple bands.

Hmmm. I was hoping to cut it once, add a balun if necessary, attach a specific length of window line or coax and pretty much be on the air.

Square vs Delta shape. Since I'm in Arizona, most stations will be east or slightly north east of us and a little over 1,000 miles away.

Maybe a horizontal delta loop supported on 3 supports is a little better way to go. Any comments here?

Does anyone know if the total length of the loop changes much when it is installed as a square vs a delta?

At this point, I'm thinking of starting out with 275' of number 14 thhn directly attached to a 4:1 balun designs dual core current balun. Then about 50-75 feet of LMR-400 to the rig.

I'm still not sure if I want to try 3 supports as a Delta, or 4 supports as a square.

Your problem is there are too many ambiguous things in all that you are talking about.

In free space, there is no difference between the delta or the square… or a circle for that matter.
Here on earth, what's underneath the antenna affects its impedance and resonant frequency.
If you change the shape of the loop and the earth is consistent AND there are no buildings or obstacles for miles around, then nothing should change either. However that is unlikely.

With all of the variables, nobody on the planet can tell you how long to make you antenna.
Start with it long and prune it to resonance.
It makes no difference if you cut excess wire out of one side or a little bit out of all 4 sides.

When I built my loops, I had the feedpoint soldered (of course) so I broke open the loop at the opposite corner (it was square).
This made it easy to take down and store.
It also made it easy at each new location to insert a piece of wire (or cut more off) from the opposite corner.

If you feed with openwire, all of that is unnecessary.
If you feed with coax, then your choice of balun is a good one.
You should only have to prune the length.
As Everette said, in order to have higher bands resonate within the ham bands, you must cut the loop for resonance on the low end of the 80m band. It is very broad-banded so that does not matter much.

The bit about "easy to match" is the real ambiguous part.
Easy to match with what?
If you compare various matchboxes on the market, they are different as night and day.
➢ Some match only 5:1 mismatches (10 Ohms to 250 Ohms)
➢ Some match 10:1 mismatches (5 Ohms to 500 Ohms)
➢ Some match up to 1200, others to 1600, and some up to 2000 or more.

An antenna with feedline length "X" might be easy to match on one matchbox yet difficult/impossible on another.

So start by telling us the impedance matching range of the matchbox you have available.

If you end up not being able to match some particular band, adding 1/8 wavelength more openwire almost always brings that band in and in many cases, just 1/16 wavelength is sufficient. Except for 80m, 15 ft. of feedline or less will bring any band's impedance into a range that can be matched.

OPENWIRE: which openwire? 450 Ohms? 300 Ohms? Well most of the feedline we call 450 Ohms is actually closer to 400 Ohms. Some even less. So when one guy specifies a length and you duplicate it, unless you are using exactly the same make an model of openwire, you won't

get the same results.

Your own suggestion on how you might start is a good one.
You already answered all the important questions.
Next step: just do it.

BTW, I didn't mean to pick on you specifically with all of the above.
I was only trying to point out why we get so many conflicting answers to what we believe is a simple question.

Gud luk and let us know how it turns out.

I have to agree with Rick it is all about what is under your wire and how close to it you are. I have worked easy 300 designs/configs of loops/ wire ant. some as close to a copy already up but over different ground in a different direction and have completely different reports per swr not even counting matching requirements be it with or with out a balun. Using ladder line, coax and or match box on a 60ft tower or on 20 to 30 ft of pc pipe everything effects the out come. And here is what it all came to if it works ie you hear who you want and can talk to them it is a working system. I have even talked and heard folks on a dang wire fence if it works and does not harm others or your equipment run with it. Do not worry so much about what others say or think if your system should not be working when you know it is, have fun . Ken

Your problem is there are too many ambiguous things in all that you are talking about.

In free space, there is no difference between the delta or the square… or a circle for that matter.
Here on earth, what's underneath the antenna affects its impedance and resonant frequency.
If you change the shape of the loop and the earth is consistent AND there are no buildings or obstacles for miles around, then nothing should change either. However that is unlikely.

With all of the variables, nobody on the planet can tell you how long to make you antenna.
Start with it long and prune it to resonance.
It makes no difference if you cut excess wire out of one side or a little bit out of all 4 sides.

When I built my loops, I had the feedpoint soldered (of course) so I broke open the loop at the opposite corner (it was square).
This made it easy to take down and store.
It also made it easy at each new location to insert a piece of wire (or cut more off) from the opposite corner.

If you feed with openwire, all of that is unnecessary.
If you feed with coax, then your choice of balun is a good one.
You should only have to prune the length.
As Everette said, in order to have higher bands resonate within the ham bands, you must cut the loop for resonance on the low end of the 80m band. It is very broad-banded so that does not matter much.

The bit about "easy to match" is the real ambiguous part.
Easy to match with what?
If you compare various matchboxes on the market, they are different as night and day.

➢ Some match only 5:1 mismatches (10 Ohms to 250 Ohms)
➢ Some match 10:1 mismatches (5 Ohms to 500 Ohms)
➢ Some match up to 1200, others to 1600, and some up to 2000 or more.

An antenna with feedline length “X” might be easy to match on one matchbox yet difficult/impossible on another.

So start by telling us the impedance matching range of the matchbox you have available.

If you end up not being able to match some particular band, adding 1/8 wavelength more openwire almost always brings that band in and in many cases, just 1/16 wavelength is sufficient. Except for 80m, 15 ft. of feedline or less will bring any band's impedance into a range that can be matched.

OPENWIRE: which openwire? 450 Ohms? 300 Ohms? Well most of the feedline we call 450 Ohms is actually closer to 400 Ohms. Some even less. So when one guy specifies a length and you duplicate it, unless you are using exactly the same make an model of openwire, you won't get the same results.

Your own suggestion on how you might start is a good one.
You already answered all the important questions.
Next step: just do it.

BTW, I didn't mean to pick on you specifically with all of the above.
I was only trying to point out why we get so many conflicting answers to what we believe is a simple question.

Gud luk and let us know how it turns out.

Subject: [SkyWires] Re: Revisiting the horizontal loop and looking for some solid design criteria

I'm pretty much going to be limited to a standard 80m loop this year, so I won't be putting up a mega-loop.

What I'm hearing is that a 80-6m loop isn't an easily duplicated antenna. Dimensions can vary widely based upon where it is being installed. There doesn't seem to be a widely accepted method of feeding the antenna where specific lengths of coax seem to work well.

I can't even find a widely accepted feed method where the length of the window line is shown to work in most circumstances. I know window line acts as a transformer and it can be pretty hard finding a specific length can be used with a tuner on multiple bands.

Hmmm. I was hoping to cut it once, add a balun if necessary, attach a specific length of window line or coax and pretty much be on the air.

Square vs Delta shape. Since I'm in Arizona, most stations will be east or slightly north east of us and a little over 1,000 miles away.

Maybe a horizontal delta loop supported on 3 supports is a little better way to go. Any comments here?

Does anyone know if the total length of the loop changes much when it is installed as a square vs a delta?

At this point, I'm thinking of starting out with 275' of number 14 thhn directly attached to a 4:1 balun designs dual core current balun. Then about 50-75 feet of LMR-400 to the rig.

I'm still not sure if I want to try 3 supports as a Delta, or 4 supports as a square.

Length of wire 84m
height 6-8m

shape of loop irregular rectangle
feed point (corner, edge, etc) middle of longest side.
type of feed line (ladder line type, coax type) Electric 1/4 wave of RG11 at 7MHz to antenna (helps lower impedance on 40m) to 20m of RG58 to shack at tuner/radio earthed there.
how is the feed line connected to the wire (balun / direct connect, etc) direct connection.
length of the feed line (this appears to be critical) see above
if you use a balun, choke or both, where are they positioned - clip on ferrites distributed along the feeder.
maybe a list of the bands used and swr readings (1:1 on 80m without a tuner)

if you use a tuner what is it and where is it placed (shack.)
if you use a tuner, are there any bands it has trouble with. 3:1 tuner can be challenged is OK on all frequencies.

People who buy a tuner with less than 10:1 matching range are shooting themselves in the foot.

We always check the typical gas mileage of any car we want to buy BEFORE we buy it.

We also need to check the matching range of the matchbox before we buy it.

Everett has done a lot of work with loops and found 4:1 GUANELLA, DUAL-CORE to work best “at the feedpoint”.

A balun in front of any tuner (in the shack) MUST always be a 1:1. If you disagree, you haven’t done your homework.

See: http://www.dj0ip.de/balun-stuff/tuner-baluns/

5212. 1400' horizontal loop

Yahoo group: SkyWires
Date: 2016-07-26 23:57:10 UTC
From: ab0re@...
Topic: 5212 Message: 5212

Hello,

I'm at my father in laws place for the week. We finally got around to installing a large horizontal loop around his property. The spacing between the poles (7 total) is 1,360', so I estimate the loop is just shy of 1400' with the wire sag take into consideration. The poles are about 35' high.

After running the loop and hooking up a short piece of coax (10') I was disappointed to see how high the swr was everywhere,. 263:1 to 23:1 on 160m, 6.6:1 to 54:1 in 75/80m, 9:1 to 24:1 on 40m, and 5.8:1 to 8.5:1 on 20m. All measurements were taken with a RigExpert AA-600 analyzer. We tried a second jumper to rule out the idea of the jumper possibly being bad. I'd be happy to send the scan file to anybody with the antscope file if they'd like to take a look at it.

Last time I made a loop we cut it for the lower part of 80m and it also had dips at its harmonics. I'm not seeing any such trends with this loop and am looking for any suggestions.

Did we make the loop too long?

Anybody else in the group have a loop of similar circumference that can share their experiences?

Any idea why 160m in particular is so miserably high for vswr?

Anything else to check?

Thanks in advance for any suggestions that are offered!

73,
Dan / ab0re

Hi Dan,

I have an 1100 ft horizontal loop and I feed it with open wire line thru a 1:1 balun and am able to use it on all bands through 6 meters with a tuner. Much better efficiency that with coax!

My 2 cents worth
Good Luck es 73

Hi Kent,

Thanks for the input. I think 1100' would be spot on for 2 wavelengths on 160m, which would perhaps equate to your success. (Our system is 2.64 wavelengths for 160m). Additionally, I've noticed the impedance of our system is quite low, which would also suggest a 1:1 balun would be a better choice than a 4:1 balun.

Open to other suggestions as well.

5215. Re: [SkyWires] 1400' horizontal loop

Yahoo group: SkyWires
Date: 2016-07-27 05:14:20 UTC
From: Andy
Topic: 5212 Message: 5215

For the 1400 foot loop, a quick-and-dirty EZNEC simulation shows the first resonance around 0.7 MHz, nothing good near the first few ham bands, and the 160 meters SWR is >100. It is very much periodic, with resonances at each harmonic, but they are not good for amateur radio.

I think it does what's expected for a loop of that length. With no attempt to be resonant, it won't show a good SWR all by itself. That doesn't mean you can't use it that way. You just need to feed it with a low-loss line (such as open wire) and add a tuner of some sort to match it, mainly to counteract the reactances due to being so far off-resonance. But if you wanted a low SWR with the loop all by itself, you would need to cut it appropriately.

For the 1100 foot loop, it looks like 2 wavelengths long just below the 160 m band.

The actual impedance would depend on where the loop is fed (you didn't say), and which harmonic we're talking about -- or how far away from resonance.

Andy

Hi Andy,

The loop is fed at the center of the southern-most leg (in platte, sd). Thanks for running it through eznec for us.

Initial indications are that if we skip one of the poles we can maybe turn this into a ~1100' delta loop which may be more favorable for the ham bands.

Hind sight being 20/20, we probably should've modeled this in eznec prior to having the telephone poles placed, but my father in law had a bunch of poles placed that allow for maximum coverage/flexibility.

I put up a 550ft delta loop and did a fine adjustment in length for good SWR on 40M. It works with reasonable dips in most ham bands so you should have good luck starting with 1100.

HELLO ,
will just share what works here, my Loop is a very Lazy looking sagging long semi square wire ,
approx, 528 to 550 ft in length,(used a roll and added to it to reach my EMT pole masts),, it is Fed with homemade ugly ladder line about 150 ft long , The feed point is about 8-10ft off one mast at about 12ft,so the wire comes down to a V, lol . I will raise it sometime to see what happens, but if it works why fix it ?
Used 12ga insulated , up about 38-40' ft , ON EMT Poles that taper from 2 1/2 up to top at 1" , loosely guyed so very flexable , If i would recommend , it would be larger diameter all the way up ,i have seen couplers some Ham OP is selling that look strong enough , and even tilt up bases .
I use an old Heathkit 2060A Tuner , which has its own Balun- 4:1 , inside , Use this Loop for 160m-10m, now not perfect on 10m but have made many contacts , I usually run 100-400 watts PEP depending on conditions .
on 13 Colonies contest , i had Clean Sweep including GB . It has been Exceptional , and dont ask for pics , Hihi, it is embarassingly Ugly ! LOL , I use an old TS930s ,has tuner, which i bypass , and an oldie Dentron AMp,,, I even lost 2 sections when my one guy on one pole mast bent from winds , and tied it off at lower height and still have Great Signal reports and asked all the time on net to be relay ,LOL

I call my Loop - The Hillbilly Loop , with Fondness ,not as an insult , LOL

Best Wishes, AJ W5HEH

ps had OCF not even close !!!!

I would think 1,150ft or 1,725ft would put you in the digital (or CW) end of 20m - 80m, if you are using insulated wire, where you may not even need a tuner. Most tuners should still tune 160m. I use 575ft (574' that stretched about a foot) and it tunes easy on all of 10m - 80m using a 4:1 balun, 160 tunes without the balun in line.

Hind sight being 20/20, we probably should've modeled this in eznec prior to having the telephone poles placed, but my father in law had a bunch of poles placed that allow for maximum coverage/flexibility.

For the 1400 foot loop, a quick-and-dirty EZNEC simulation shows the first resonance around 0.7 MHz, nothing good near the first few ham bands, and the 160 meters SWR is >100. It is very much periodic, with resonances at each harmonic, but they are not good for amateur radio.
I think it does what's expected for a loop of that length. With no attempt to be resonant, it won't show a good SWR all by itself. That doesn't mean you can't use it that way. You just need to feed it with a low-loss line (such as open wire) and add a tuner of some sort to match it, mainly to counteract the reactances due to being so far off-resonance. But if you wanted a low SWR with the loop all by itself, you would need to cut it appropriately.
For the 1100 foot loop, it looks like 2 wavelengths long just below the 160 m band.
The actual impedance would depend on where the loop is fed (you didn't say), and which harmonic we're talking about -- or how far away from resonance.
Andy

5223. For Sale 2KW 4:1 Dual Core, Current Balun (200/50 ohm), with CMC Chokes.

Yahoo group: SkyWires
Date: 2016-08-25 14:38:56 UTC
From: everettsharp@...
Topic: 5223 Message: 5223

I have for sale 2 each;
2KW 4:1 Dual Core, Current Balun (200/50 ohm), with CMC Chokes.
I am asking $110 each, which includes the shipping to the lower 48 states, I also have 3 smaller ones that are also combination of a 4:1 balun and a CMC choke and should be good for 500 watts. I am asking $80 each, which also includes the shipping. I don't think that anyone is building any commercial versions of these baluns?

If any one is interested please contact me off list at everettsharp@aol.com. I can provide more detail if interested,
.Everett N4CY

Yes...very Similar to NVIS with counter poise. It turns it into a horizontal cloud warmer. This can be very good (depending of freq and propagation) to firm signal up closer in to your qth.
   Hope this helps 73 Lee

Is that something like what's described here?
http://www.w9xt.com/page_radio_gadgets_nvis_antenna.html

How do you know this short reflector is really doing anyt hing? Depending on the height of the loop, how do you know the fine performance is not just the cloudwarming nature of the main loop near its fundamental frequency when it's horizontal?

5229. Re: [SkyWires] anyone here used or hear of loop under loop to ground ?

Yahoo group: SkyWires
Date: 2016-08-29 21:44:49 UTC
From: Evan
Topic: 5226 Message: 5229

AJ,

Sounds like that information is a bit sketchy if not incorrect. First, if one wanted to have a reflector loop under a "driven loop", a lot depends on spacing, NOT just that 8-10 ft off the ground but also the spacing between the driven loop and the reflector, which is a function of wavelength. That "5-10%" figure is incorrect and if anything, it might be 105-110% BUT that has to be approached from the standpoint of the change in the wavelength of the reflector loop based upon proximity to ground. Connecting it to a ground rod is of questionable benefit unless one is concerned about static buildup perhaps.

I've been experimenting and using horizontal loop antennas for almost 30 years and have found them to be quite satisfactory for my operating activities. For those that believe they can't be used for DX, I've worked Antartica, Canary Islands, Italy on a regular basis, Belgium, Germany, India, etc. etc. While not a DXer, I have worked some DX but haven't really tried.

There is a lot of info on the Internet about horizontal loop antennas, and some of it is even correct!

73,

Evan, K9SQG

Ham radio, like many things in life, has no free lunch. A reflector under a horizontal loop might help to reduce ground loss depending on local terrain. But the "price" one might pay is changing the radiation pattern. Though not strictly comparable, if one looks at the pattern for a single quad loop, and then a loop with a reflector, one can readily see the difference in radiation patterns. When reflecting reflections via the overhead ionosphere, one can see that altering the incident wave will indeed affect the reflected wave. Whether this is good or bad depends on one's operating goals.

If one has reasonable ground conductivity, a reflector element wouldn't help dramatically, with poor soil it would IF tuned as a reflector for each and every frequency used. I would imagine a chicken wire ground screen, in a pattern just under the antenna and laid on the ground, would help for poor soil conductivity. Based upon my measurements, a 1-2 S-unit reduction in noise is a great benefit with the loop!

5236. 500 Watt Balun/Choke For Sale

Yahoo group: SkyWires
Date: 2016-09-29 11:05:25 UTC
From: everettsharp@...
Topic: 5236 Message: 5236

I just finished building 4 more of my 500 watt 4:1 current balun/choke combinations. The design uses 2 F150K cores for the 4:1 balun and a FT140-43 core for the choke. They are all enclosed in a very nice compact package that weights 15.4 oz. All of the hardware is stainless steel and the UHF connector has a Teflon insulator.

The 4:1 balun is wound with 16 gage Thermaleze-Coated Magnet Wire with a Teflon sleeve over the wire. The common mode choke is wound with 17 turns of RG316 coax. I am asking $85, which includes shipping, one of the 4 was sold so there are still 3 left. These will more than likely will be the last that I build to sell. If interested please contact me off list at everettsharp@aol.com. Everett N4CY

5237. New here: A Few Questions....

Yahoo group: SkyWires
Date: 2016-10-03 22:29:59 UTC
From: dustin.willett@...
Topic: 5237 Message: 5237

Hello all - I will be installing a full wave loop on the top of my county courthouse sometime in the near future for EOC/Auxcomm work. I have a few questions (both mechanical and theoretical):
I have read a few comments that reference using a weighted pulley system to both keep tension as well as build in a little "give." I like the concept/idea, but I'm not envisioning how the actual mechanical system would work. Does anyone have a simple diagram that shows how this works? I have a 1000' spool of No. 13 Poly-Stealth antenna wire - I've read several opinions regarding actual length of a full 160-meter loop due to differences in velocity factor, etc... including one very specific reference/preference for 574'. My intent is to erect an antenna that works across as many HF bands as possible, not singling one out specifically at the expense of another. Any thoughts on how many feet of wire would be optimal? I've read/researched a bit, and it seems like there are several folks who go the 4:1 route and several who prefer the 1:1. I'd like to hear anyone's preferences.

I have some challenges that have limited some choices in my design (how far I can run ladder line, etc...), but these are the supplies I currently have on hand (I am willing to consider other options, if there is good cause): the ends of the loop will run approx. 20ft to an Array Solutions 309H surge suppressor via DX Engineering 300ohm ladder line, from there I have a run of approx. 100ft to a Balun Designs Model 1171 - 1:1 ATU Current Balun. I'm currently planning on making this run with doubled 93-ohm RG-62 in a shielded balanced line configuration (By necessity, I have to run through quite a bit of 3/4" EMT, hence no ladder line). Then a short 3' piece of LMR 400 from the 1:1 balun to a Palstar HF-Auto tuner (8:1 matching) and finally an ICOM 9100.

I'd be interested in hearing pros/cons regarding the radio/tuner-side 1:1 current balun with the doubled RG-62 out of the building versus running LMR 400 from the radio/tuner out of the building to an antenna-side 4:1 balun?

I apologize if I've asked for too much heavy lifting - I am the first to admit my weakness in theory and I have gotten quite muddled trying to design this system - any help would be greatly appreciated!

5244. Where does the loop radiate?

Yahoo group: SkyWires
Date: 2016-10-12 20:52:28 UTC
From: rzar66@...
Topic: 5244 Message: 5244

Hello all.

I'm new here and also a new ham. Last weekend I put up an 80m tilted horizontal loop in my back yard and it is working great. Was able to work Brazil, Puerto Rico, Alaska, and Canada. This being my first HF antenna I am very happy with it so far. The shape of my loop is nearly a perfect square which has me wondering, does my antenna radiate from all sides of the antenna? Do all sides radiate equally? I understand that the loop is omidirectional but is that because all sides of the square radiate?

Thanks
Ryan

Ryan,

Not sure I would call the antenna omnidirectional. Why? It depends on a lot of factors including the frequency (and I'll assume you are talking about the fundamental), terrain under the antenna, ground conductivity, buildings or objects in the region, etc. etc. You're best bet is to look at idealized radiation patterns from computer models. LB Cebik, W4RNL, has done extensive work in this area and his findings are available online and in his books. Generally speaking the antenna is radiating straight up and, depending on the vagaries of the ionosphere, it will radiate in many directions. However, there might be nulls and such. In general you can consider it somewhat omnidirectional on the fundamental, and as a generalization it will probably apply to your antenna.

I've been using and experimenting with horizontal loops for over 25 years and have found them suitable for my operating preferences.

Subject: [SkyWires] Where does the loop radiate?

Hello all.

I'm new here and also a new ham. Last weekend I put up an 80m tilted horizontal loop in my back yard and it is working great. Was able to work Brazil, Puerto Rico, Alaska, and Canada. This being my first HF antenna I am very happy with it so far. The shape of my loop is nearly a perfect square which has me wondering, does my antenna radiate from all sides of the antenna? Do all sides radiate equally? I understand that the loop is omidirectional but is that because all sides of the square radiate?

Thanks
Ryan

Evan,
Thanks for the explanation. I guess what I meant was is the whole 260 feet of the wire radiating around my square shape loop when I transmit?

Ryan,

I think the direct answer is "yes" but I've read or have been told that they usually radiate stronger in the direction opposite the feedpoint but many folks here have much better knowledge on this than I.

/"I guess what I meant was is the whole 260 feet of the wire radiating around my square shape loop when I transmit?"

Skip,
That's what I've read also. That's a good thing for me since the opposite of my feed point is the highest point of my loop. Just worked a station in Colombia on 10m with only 5 watts.

Same principles apply to manual tuners. It all depends on the antenna system, bands of interest, and the resulting impedance of the antenna system, resistive AND inductive components. Then it is a matter of whether or not these fall within the matching range of the tuner. Unfortunately, the manufacturers rarely tell you the reactive matching range and instead just talk SWR or the resistive component. Makes the decision process a tad bit more difficult but that's what happens when marketing overpowers the technical folks.

Mark,
I have had an 80M HFWL for years. As its low it is a "cloud warmer" but good for NVIS on 80m but also does work some DX. No tuner needed on 80m. I have used it on all bands with 3:1 internal tuners and coax feed.
40m has the highest impedance so I have a quarter wave section of 75ohm coax in line to help the tuner.
With a 10:1 tuner it is not needed.

Thanks gentlemen. I continue to do more research.
I did a very rough sketch of the layout of my wire route and it turns out to be around 288ft long from end to end, in a sort of trapezoid shape. Since I don't do anything on 160, I figure I should tune up well on the other bands. I own a MFJ 948 (949E w/o the dummy load) and am hoping, by all I have read, with its internal 4:1 balun, it should suffice my tuning and connection requirements. So with that, I am going to give that a try first before making an expensive (to me) purchase. If not, I have friends with other tuners I can try by bypassing the 948's tuner features and using the others to match up.
I am sure it'll work pretty well locally with NVIS on 80m, but am hoping to get out a little ways. I discovered the digital modes last year so am also hoping to finally get a card from Europe.

I was wondering how much curve (if any) would I be able to get away with when installing my beverage antenna. I've 5 acres and there are good sized oaks and pecan trees which are laid out somewhat in a question mark configuration. I could run the wire at about 10' high for a distance of 600'. The last 300' would be rather straight. Any advice? Thanks Russ K5ZZR My Heroes Wear Combat Boots! 5254. New problem with an old loop

Yahoo group: SkyWires
Date: 2017-03-19 16:13:45 UTC
From: slr_65@...
Topic: 5254 Message: 5254

Hi Guys,

.

My loop has been up and allowing me to work the world for a quite a while now, but now I've ran into an issue with it I'd like some help with.

.

My loop is just a length of #12 THHN stranded copper wire shot over a couple trees in my front yard, about 250' in diameter, about 45' high at the highest and 12' high at the lowest. It tilts to the north and is fed at the north (lowest) end with a ladder-lock and 450 window line. The window line is about 25' long. Not an optimal install I realize, but it works very, very well.

.

I can tune it from 80 through 10 with a Dentron Super Tuner with it's internal 4:1 voltage balun (20meter is picky), with a 1:1 Balun Designs tuner current balun (20 meter is picky), and with a Balun Designs 4:1 current balun (20 seems to behave better with this balun).

.

I'm low vision so following a recommendation here, I picked up an MFJ 993b auto tuner. It's worked a treat! With it's internal 4:1 current balun it tunes everything without issue, in fact it will find a match on 160, though I never operate there as it's abviously waaay too short (I rarely operate 80 as I'm near some power lines that generale a lot of noise, though I do occasionally operate there, so I'd like to continue to be able to). I've been very, very happy with it.

.

I recently picked up an Ameritron ALS-600, which will exceed the limits of the 993, so I picked up it's big brother, the 998. WOW! It's BIG! It doesn't have a built in balun. With the 1:1 balun it will tune 40 and 20, and that's it, it'll either rattle the crap out of the relays and never find a match, or it won't even try, it just gives the "Huh? Increase Power" message on the other bands. With the 4:1 balun it will tune 20 through 10, but not 80 or 40, on 80/40 it again either rattles the crap out of the relays and never finds a decent match, or won't try and gives the increase power message.

.

Though the specs are almost identical, it appears the 998 doesn't have the range the 993 does, which is disappointing...I've become very spoiled with my 993, I have the rig interface, so I just switch bands and hit tune and listen for the beep and I'm good to go.

.

I'm going to dig in a little further tomorrow. I'm using a Kenwood TS-590SG with the MFJ rig interface, so I don't have control over the power level when it tunes. I'm wondering if I send a CW carrier with a little extra power if it won't over come the increase power message, I've read that message displays when there's a big mismatch as it's not sensing enough power to trigger a tune. Possibly if I can over come this and get it to tune, then next time it will know where to start and will work with the rig tune button?

.

I could also just put each balun on it's own input to the tuner and then use a knife switch, relays, etc. to switch the antenna to the appropriate balun. That's livable, but still doesn't get me 80 meter.

.

I'm low vision, but not no vision, so if I have to manually tune I can, but again, I'm just spoiled with my 993!

.

I've considered seeing if I could use an Arduino microcontroller to get a more accurate setting dislay on the Dentron - basically interface belt driven potentiometers to the shafts and just read the pot voltages, that should display the settings very accurately. I dunno if RF inside the cabinet would be a problem though.

.

I'm also wondering if a differential T tuner, like the MFJ-986, with it's inherent easier/faster tuning wouldn't be a good choice. I have noticed that my 993 often finds a 1.0 match, but when transmitting it may show a 1.2 or 1.3 match. I've never worried about it as with 100 watts that's trivial, but I've read the solid state ALS-600 lives longer if you keep the SWR below about 1.4 (if I recall, it's safety mechanism kicks in around the 1.8 to 1.9 range). I've noticed in the past that if you tune at 10 watts and then increase power after you find the best match that often the SWR will increase a tad and you can tweak again at the higher power to get the best match, I wonder if this wouldn't be a good habit to get into to make sure the very best match is presented to the ALS.

.

I have a SARK 100 antenna analzyer, but it's on loan to a friend right now. I'll have it back shortly and will run some sweeps if that will help form a plan.

.

Not a huge issue, I'm not off the air or anything, it's just that I've been able to work all the bands very conveniently, and now with the amplifier in the mix things aren't working so smoothly and I'm just trying to find the smoothest path.

.

Thoughts, comments, suggestions?

.

73,

.

Steve, KA0NEB

I dunno Joe...I LIKE my 993 and I don't really want to release the magic smoke from it! I'm low vision...popping the cover off and troubleshooting / fixing what broke isn't that easy for me these days, and MFJ tends to OVERstate their specs, nothing in that makes me want to see what it can actually handle.

.

I took a tower down last fall and hope to get it up this year with a beam, so if I have to forgoe the amp for a bit, that's fine. Or, if I have to switch baluns with a knife switch, or do a quick tune on a manual tuner, I could live with that.

i would try to add a few metres extra of the ladderline and then see if it better finds a match ...

sometimes with a multiband antenna you are either on a very high or low impedance spot that the tuner can not handle

a few metres of ladderline will shift the impedance "around the smith chart" and you will then find a match with your autotuner

...

i have a fullsize topbandloop (168m) ... works from 160-10m with a low swr ...

on some bands i add an extra length of ladderline to have a better match on the shack end (and so tuner has lower work to do and so lower loss in the complete system)

ladderline has such a low loss that it will not hurt your signal ... in fact with a LONGER line you can have higher signal cause the ladderline adds fewer loss as a tuner would do with very hard to tune impedances

greetz

sigi dg9bfc

ps cause the tuner has to tune the sytem anyway you can make a test setup with adding some single wire with spreaders ... no need to use windowline ... just grab some wire out of your junk box and hold the 2 wires at an inch or two distance with some pvc tape stripes as "spreaders" ... if it works ok then you can go and buy some additional windowline

Ah, I'd forgot that Sigi! When you don't use it, you lose it, and the loop has been working so well I haven't looked at antennas in a very long time. I'll try adding some on and see what happens. I've actually been considering running the loop a little differently, I think I can get it a big bigger, and if I do that then the feed point will move from the lower north end to the sloping west edge and the feed will get longer.

I'll play and report back, thanks!

Steve, KA0NEB

Hello Steve,
My thoughts for your situation.

If you are using open wire ladder line (homebrew works best) perhaps a true balanced tuner, by way of example the Palstar at http://www.palstar.com/en/bt1500a/ may be a better tuner for your problem because it allows the capacitor to be connected to either side of the coils and allows Hi Z or Lo Z looking into the feedline. This will be beneficial to all HF bands for adjustment with lower tuner loss for a 1 wavelength 80m loop that is not very high. Changing the feedline length and/or adding a few feet to the loop can work but without modeling it, it may result in “this band or that band” with lots of fumbling.

Additionally, with the balanced tuner you do not use a balun at the output side of the tuner but rather a 1to1 balun on the input side (rig to tuner) which provides best efficiency for both the balun and tuner. - But, autotune adjustment is out of the question for a balanced tuner unless you spend a fortune.

Given the low sunspots to be with us, if you are considering a tower again, the likely presumption is that it will serve 20m, 17m, 15m, 12m, 10m and perhaps 6m.
and you may find that 160m, 80m and 40m may become your primary interest which would lend to the idea of better loop performance on those bands for the near future. - Hence a balanced all band tuner.

Your comment of:
[[I have noticed that my 993 often finds a 1.0 match, but when transmitting it may show a 1.2 or 1.3 match.]]

This may not be cause for concern because SWR meter diode characteristics are such that as the reflection side diode input voltage increases and exceeds the “zener knee operation” of the diode the diode response becomes more linear as the voltage increases.

If on the other hand the SWR goes much higher this could indicate component break down in the antenna system or spurious output from the transmitter at other frequencies which is not resonant causing additive reflection as power is increased.

Just thinking with my fingers on the keyboard here.

Hi Hank,

.

I really want automatic, but if I gotta manual I'd prefer as few knobs as possible, I think a differential T tuner would work as my Dentron does it well enough and is also a T tuner.

.

The annoying thing is that my 993 tunes this without issue. I didn't have much time tonight, but I put the external baluns on the 993 and it tunes with them just fine, the 1:1 seems to be a little pickier, but it still works. The specs on the two are almost identical, but evidentally the 998 doesn't have the range the 993 does in actual use.

.

I have a tower already, I'm just waiting on warmer weather to install it, so yeah, 20-10 will be handled by it, though I may do something for 40 on it too. Sooo, in the near future I'll just have to tune for 80 and possibly 40, so this won't be as much of an issue, but still...I'm spoiled by my 993 and simply LIKE auto tune!

.

I'll dig in deeper in the next few days. I got my SARK analyzer back, so I'll refresh myself on how to run it and take a few sweeps and see exactly what's being presented and then see if it can help make more of an educated guess on any adjustments.

.

Thanks! I'll post back as I investigate/experiment a bit more, 73,

.

Topic: 5254 Message: 5263

Hi Guys,

I'm just getting back to this...had a small bout with pneumonia.

I have a Sark Mini 60 and the last time I used it Z-Plots worked fine, and I liked using it. Since then it seems the COM port for it has moved up to 13 (I diddle With Arduinos, Teensys, etc. so I imagine something there caused things to move).

All the Windows based software talks to it fine, but Z-Plots will not - gives an error writing the output file, says no data received, and the unit never goes into scan. Does Z-lots have issues with COM ports in the double digits?

Thanks!

Steve

5264. Re: New problem with an old loop

Not amking much progress on this tonight, I decided to install the drivers for the SARK on my shack computer, a 32 bit Win 7 machine and they're refusing to install - it says it did it, but it's not done, nothing changes in my device manager. Sigh...I bought the SARK almost two years ago, played with it a good bit, it worked fine, and now that I need it it's fighting me all the way! GRRR!

5265. Now THAT'S a Loop Antenna!

Yahoo group: SkyWires

Topic: 5265 Message: 5265

I have just got back on HF after moving to a new QTH last August and finally finding a dry day (hey, it's Oregon) to get my hexbeam assembled. My skywire loop will go up later this summer.

As I saw that the conditions were open yesterday afternoon on 20m, I thought I would see what and who was on (note: the hexbeam is still sitting on the ground in my back yard waiting for a new rotor for the roof mount...).

On 14.277 (I think it was) I heard a voice and thought he was in the same room. If you haven't heard him before, you will! W0JEE was booming into my radio in NW Oregon from south central TX! I looked at his QRZ page and saw his photos. Four, 110' high salvaged oil pipe painted bright red. 300' apart on sides, in a square pattern. At over 1150 feet in total length, it's basically a double wave 160m loop. What a signal! I am sure he was running some wattage through it, but I was blown away. Plus, do the math - at 20m it become a multi-wave wire. It was amazing.

Check out his page and see his story! Love this hobby! 73s!

Mark - KB7OOM (new vanity call application pending)

Let's not spread the word about the horizontal loop that some of us use. Of my two loops, the 80 M one is mostly at about 20 ft high. I'm not a DXer but have worked South Africa, Germany, Italy, Canary Islands, and a lot of states on a regular basis, on 80 M SSB. Let's keep it a secret so WE can work the DX, hi hi.

73,

Evan, K9SQG

5268. Skyloop vs Delta Loop for 80 and 40

Yahoo group: SkyWires
Date: 2017-04-07 15:13:21 UTC
From: maxrcul@...
Topic: 5268 Message: 5268

The tallest structure on my property is my self supporting 45 foot tower which sits 65 feet from the house. The roof peaks at about 22 feet. All of the trees are ornamental with none exceeding 10 feet. Herein lies the problem - how do I support a horizontal loop? The xyl has "banned" guyed masts of any type so whatever I put up has to be free standing.

A sloping delta loop with the apex at the top of the tower and the other two corners supported appx. 10 feet off the ground is another possibility. Compared to a horizontal loop, how much less effective is a delta?

I've had several contacts from guys using an antenna from Radio Works called the Super Loop 80 or Super Loop III which only require two supports. I'm a little skeptical about some of the claims I've heard about this antenna.

Your guidance and wisdom would be greatly appreciated.

Bill - W3PNM

Topic: 5268 Message: 5269

Bill,

There are so many site specific variations that it is difficult to transfer one ham's experiences to another. However, the tilting delta loop has been covered by W1FB (SK) in his antenna book, and possibly by LB Cebik (SK). General consensus is that the tilting delta loop is not overly directional and works well for DX, with W1FB said it equaled or exceeded performance of his tribander at 50 ft in almost all instances. There are variations in terms of feeding it but I do believe it is worth pursuing.

Now, let's see what the experts say. I suspect they will be encouraging. As a side note, my horizontal loops work fine for my operating needs and particularly enjoy the noise reduction they provide.

Hope you can make it here for Hamvention.

73,

Evan, K9SQG

Bill,

You are being overly concerned about this. For 80 m and 40 m your antenna will be too low, wavelength wise, from the ground to conform with the most wonderful and ideal 'standard' patterns. You will get whatever pattern you get with the physical constraints that you have. Just put it up and enjoy whatever you work. BW

Back before I moved to my current location back in 2012, I had a loop up, it was about 520 - 530 feet long and maybe about 20 feet off the ground, that was about as high as my son and I could get it with a roof snow rake, up and over and around trees. Maybe the only saving factor, the 12-gage wire still had the coating on it.

I know it was FAR from being prefect, but it got me on the air and when the bug bit me, I would work the occasional DX that I hadn't heard before. Now where I am, no trees so that is out of the question and I doubt my HOA would like to see towers up all over the yard, I couldn't afford them anyway. I will eventually put up a Dipole for 80 meter, then I can use my tuner to make it usable for the other bands I want to use.

Not trying to influence you or anyone one, just sharing what I did. Most of the time it worked 'good enough' for me and in my opinion, that was what I was after. As 'they say', your mileage may (most likely will) vary.

Dave,
I have always wanted to try putting up a wire around the edges of the eves of the house. This will vary, of course, on the size and footprint of your home. My last home, a loop would have been only maybe about 120ft long, but it would have been 20ft up on the air on the second story. I now live in a flat house, but the lenght of the loop would be close to 190 ft, albeit only 10 ft up. Trade-offs I guess, but if your dealing with HOA, it may be "good enough" to get on the air.

I started with an inverted V cut roughly for 3.885 with the apex about 35' in a pine tree. Didn't work very well, so I hung a 80M dipole across my 100 ft wide lot. It was only about 10 ft off the ground, so, it didn't do so good either. I decided to tie the ends of the inverted V to the ends of the dipole. Now, I have a delta loop fed with 600 OHM OWL at the bottom center . My most recent contact was on 14.286 using AM at a power level of 7.5 watts with K3PID @ 17:45 UTC. That's about 1100 miles from my QTH in Portland, ME + mileage up to and back from the ionosphere. The wire is 14ga stranded insulated copper. Built in ATU on my KX3.

So, low hanging loops do work. DE, K4TQF

No.

Both my inverted V and the 80M dipole started out as end fed wires with a 9:1 Balun in a box with a coax connector. They were about 70 feet long. I hung the first one up in the tallest tree I could climb and added another 70 ft wire to the counterpoise connector, leaving the balun in place and using RG-8 coax to feed. I already owned the other end fed setup from my former QTH, so I extended the counterpoise using the old 468/f calculation, trimming it down to about 60ft (120' total). Unfortunately, that left the ends of the dipole hanging down as my lot is only 100 ft wide. I knew it wasn't going to perform well when I put it up. (Remember, I'm running an Elecraft KX3 with no amplifier) That's when I decided to tie the inverted V and the dipole together to make the loop. (The ends of both antennas wound up in the same trees) I also removed the 9:1 baluns and went to 600 ohm OWL feeding the loop at the bottom center. I guess you could say my method is "throw it against the wall and see what sticks". My best guess is about 240 feet of wire in the air. I made the ladderline using spreaders from 73CNC.com.

From this QTH, I have made contacts with Arizona, Oregon, & Europe, but I was using SSB at full power (15 watts). I suspect the stations on the other end of those contacts were doing the "heavy lifting" with big towers and beams. I mentioned my AM contact, as I thought that it indicated what one could do with less than 10 watts, in the middle of the day on 20M. With our current poor band condx.

Tnx for most interesting story.
Your 241 ft at 1005 leads to lowest resonance near 4.15 MHz.

I will be connecting two almost parallel doublets, one 135 ft long, the other 100 ft long about 40 ft apart, so will be looking at possible maximum length available of 235+40+40= 315 ft, which if used would be
just below 3.2 MHz.

I could also adjust wire in the air to the classic 287 ft for 3.5 MHz lowest operating frequency.

Any suggestions, based on your experience?

Thanks,

73,

Ed McCann

Thanks for comments Mike.

Longer wires run East-West, shorter ones North-South.

Was a bit more interested in using my Measures design Balanced-Balanced Tuner on all bands with ladder line fed loop cut for lowest band (1005/3.5 MHz = 287 ft loa).

Notion of two element wire beam on 75/80 is appealing, and on the bucket list for experimentation.

Would be nice to know what's going on with your phase shifting.

Otherwise, I have an old Johnson 275 tuner with true balanced outputs. Looking into the Johnson with my AEA VIA-HF analyzer, I get a 1:1 tune on both bands. It's a little sharper @ 3.885, but still 80KHZ wide at about or less than 1.25:1

I have a two pole knife switch on my feedline so I can reverse the phase. Don't ask me why, but reversing the phase, even with my loop setup, will make the difference between a "barely copy" to a "solid copy".

Hello group,Evan, K9SQG has it right..paper antennas make no contacts,the charts,graphs and patterns are interesting but how will they relate to your antenna?...Put something up even if it is a compromise!After you have it "UP" you can get a reasonable idea of performance by using the tools available to give you an"objective" look at how it is performing.My 284' loop is about 30 feet high, and all in the backyard. It keeps the neighbors and the XYL happy as it is barely visible from the street .It is fed with 300ohm slotted line via a 4 to 1 balun.
.. I wanted to do an objective look at how it was performing and set up this winter to find out. .Operation was between October and April. Using 40 watts(high power) on digital modes JT65 and JT9(WSJT-X) using PSK reporter and Hamspots to give real time performance checks from stations all around the world with real signal level reporting.. Qsomap will give a graphic view of where the signal was copied.So, how did it do? I worked all bands from 10 to 160 except 60 meters.Most of the contacts fell inside the 5000mile circle with some in VK,ZS,and JA out to 10000 miles. I will attach a map of where the contacts were, it covers all bands.. I was spotted by stations that I didn't work but they are not shown on the map. The one "hole" was in central Asia/china/India, basically north of this QTH where I had no contacts.As an interesting aside , on 40 meters it is not unusual for me to have spots from Europe,South Africa and North and South America at the same time so, fairly omni directional I'd say!
This was my normal operating..no contests and I probably would have had more western states on 80 if I had stayed up later...HII have to admit I am very pleased with the performance of this antenna, it is the latest in a line of Hloops going back to the late 1960's and confirms my belief that the large loop is a great all band antenna and one capable of good performance at modest heights.
